

SKELETAL-TARGETED RADIATION TO TREAT BONE-ASSOCIATED PATHOLOGIES

5

RELATED APPLICATIONS

This is a continuation-in-part of U.S. patent application Serial No. 10/172,363, filed June 14, 2002, which is a continuation-in-part of Serial No. 10/014,335, filed December 11, 2001, and also claims priority from
10 provisional U.S. patent application No. 60/300,673, filed June 25, 2001; Serial No. 10/014,335 is a continuation under 37 CFR § 1.11(a) of PCT Application Serial No. PCT/US00/16052, filed on June 12, 2000 and published as WO 00/76556 on December 21, 2000, which claims priority from provisional U.S. Patent Application No. 60/139,065, filed June 11, 1999, 60/143,780, filed June
15 13, 1999 and 60/149,821, filed August 19, 1999, all of which applications are incorporated herein by reference.

BACKGROUND OF THE INVENTION

The use of agents which cause partial or total suppression or eradication
20 of bone marrow has become an accepted part of certain procedures used to treat patients with cancers such as leukemias, lymphomas, myelomas and Hodgkin's disease as well as in the treatment of patients suffering from hematopoietic disorders such as sickle cell anemia and thalassemia. In situations where the patient is suffering from a hematopoietic disorder such as thalassemia or sickle
25 cell anemia, bone marrow transplantation may offer the possibility of a cure. If the abnormal bone marrow of an individual suffering from sickle cell anemia or thalassemia can be eradicated and then replaced with a bone marrow that takes and is reproduced and capable of producing normal red cells with normal hemoglobin, the individual may be cured.

30 Multiple myeloma is a disease of abnormal plasma cell proliferation that can result in anemia, pathologic fractures, renal failure, and death. Complete eradication of the abnormal plasma cells and precursor abnormal cells that may

differentiate into abnormal plasma cells can prevent the progression, reverse or even cure the disease.

Current therapy is high dose chemotherapy (with melphalan and prednisone, or combinations such as thiotepa/busulfan/cyclophosphamide) with or without total body irradiation (TBI). Treatment with melphalan 140 mg/m² of body-surface area given intravenously can induce partial or complete remissions in about 40% of patients. However, it causes severe and sometimes irreversible myelosuppression. For example, see B. Barlogie et al., Blood, 72, 2015 (1989); (1998); D. Cunningham et al., J. Clin. Oncol., 12, 764 (1994); R. Bataille et al., New Engl. J. Med., 336, 1657 (1997).

Furthermore, when radiation is combined with other cytotoxic therapies, such as chemotherapy, the toxicity can be additive or synergistic. In addition, patients who undergo bone marrow suppression or ablation, sufficient to require either growth factor support, transfusion support or stem cell reinfusion, may encounter toxicities from the chemotherapy, from TBI, or both.

The dose of chemotherapy and radiotherapy that can be administered to an individual patient is often limited by patient age or overall health. Some patients who could benefit from high dose chemotherapy and radiotherapy do not receive it because they are considered too old or have other concomitant diseases which make them unsuitable candidates because of the non-target organ toxicity currently associated with these therapies. Higher doses of radiation may increase the percentage of tumor cells that are killed, and, with ionizing radiation, there comes a point where small increments in radiation can have a major impact on the percentage of cells killed. Regardless of the type of initial chemotherapy regimen, all patients will relapse and the five-year survival rate is usually less than 30%.

The use of complexed radionuclides for bone marrow suppression is discussed in U.S. Patent No. 4,853,209, where the use of Samarium-153 (¹⁵³Sm), Gadolinium-159 (¹⁵⁹Gd), or Holmium-166 (¹⁶⁶Ho) complexed with a ligand selected from ethylenediaminetetramethylenephosphonic acid (EDTMP), diethylenetriaminepentamethylenephosphonic acid (DTPMP), hydroxyethylethylenediaminetrimethylenephosphonic acid (HEEDTMP),

nitritotrimethylenephosphonic acid (NTMP), or tris(2-aminoethyl)aminehexamethylenephosphonic acid (TTHMP) is disclosed. Phosphonic acid-containing chelators are selected due to their ability to target the radionuclide to the bone. J. H. Turner et al., J. Nat'l. Cancer Inst., **85**, 1508 (1993), report that ^{153}Sm -EDTMP used with melphalan, followed by bone marrow transplant, improves survival of rats inoculated with murine myeloma cells.

U.S. Patent Nos. 4,882,142, and 5,059,412 are directed to a method for the suppression of bone marrow and to a composition for use in the method. The method comprises administering to a mammal in need of such treatment a bone marrow suppressing amount of at least one composition comprised of a radionuclide ^{153}Sm , ^{159}Gd , or ^{166}Ho complexed with 1,4,7,10-tetraazacyclododecanemethylenephosphonic acid as the macrocyclic chelating moiety. The method of bone marrow suppression described therein may be used in combination with chemotherapeutic drugs and/or external radiation. The compositions comprise the radionuclides in dosages comprising from about 18 to 1850 megabecquerels per kilogram of body weight of the target mammal. The amount of radioactivity delivered to the bone is necessarily lower, and was not determined.

Therefore, a continuing need exists for methodologies and agents useful for selective bone marrow suppression and/or for adequate tumor cell killing, that is, wherein the bone marrow is suppressed and/or tumor cells killed with only minimal damage to non-target soft tissues, for example, liver, urinary bladder, and kidney. There is also a need for a means of delivering high radiation doses to sites of disease in or near bone, with standard or high dose chemotherapy without increasing toxicity to non-target organs. For those situations where bone marrow support can aid in therapy or cure, it would be desirable to have a means of first selectively suppressing the abnormal or diseased bone marrow independent of, or with limited, total body irradiation.

SUMMARY OF THE INVENTION

The present invention provides a method for selectively, rapidly, and effectively suppressing bone marrow or to treat a pathology associated with (in or near) the bone or bone marrow. In one aspect, the method comprises
5 administering to a mammal in need of such treatment a high dosage of a complex of a bone marrow suppressing radionuclide with a bone targeting ligand, such as an aminophosphonic acid. Such pathologies include cancer, autoimmune diseases, certain infections and certain hematopoietic genetic disorders.

Preferably, the radionuclide is ^{166}Ho and the ligand is a macrocyclic
10 aminophosphonic acid such as DOTMP. Another preferred complex is ^{153}Sm -EDTMP, which is commercially available as QuadrametTM from Cytogen ($^{153}\text{Sm}^{+3}[\text{CH}_2\text{N}(\text{CH}_2\text{PO}_3^{-2})_2]_2$). It is approved for use in palliation of pain in metastatic bone tumors. The complex is preferably administered in a single treatment dose effective to deliver at least 20 Gy to the bone marrow of the
15 subject. The present invention also provides aqueous compositions comprising ^{166}Ho -DOTMP or ^{153}Sm -EDTMP and a radioprotectant that are stable for at least about 72 hours under ambient conditions.

A preferred embodiment of the invention provides a method to increase the efficacy of chemotherapy, particularly high dose or intensive chemotherapy,
20 without a substantial increase in total side effects, such as urinary tract side effects, and more preferably, without the need for TBI. This method comprises administering an effective bone marrow suppressing amount of a radionuclide-amino phosphonate complex to a subject in need of such treatment in conjunction with one or more chemotherapeutic agents, while maintaining an
25 acceptable level of tolerance of the subject to the total therapeutic regimen. For example, it has been unexpectedly found that a high dosage of radiation can be delivered to the bone marrow of a subject afflicted with a bone-associated neoplasm (cancer) or non-cancerous myeloproliferative disorder in conjunction with high dose chemotherapy, such as melphalan in the case of myeloma, while
30 not substantially increasing the side effects as compared to the side effects associated with the high dose chemotherapy alone. This regimen is particularly

effective in patients who are refractory to, and in relapse after, conventional primary therapies, such as those listed in Exs. 17-20 below.

For example, the use of at least about 200 mg/m² melphalan to treat multiple myeloma, particularly refractory multiple myeloma, can be combined with a dosage of a ¹⁶⁶Ho or ¹⁵³Sm aminophosphonate complex effective to deliver about 15-30 Gy, and up to about 30-50 Gy, to the bone marrow of the afflicted subject without substantially increasing the side effects over those associated with melphalan therapy alone at about 140 mg/m² or about 200 mg/m². Such treatment has the advantage of providing efficacy comparable to that obtained from treatment with a combination of melphalan and TBI, without the side effects associated with TBI.

It was unexpectedly found that a relatively low dose of ¹⁶⁶Ho-DOTMP (≤ 30 Gy marrow dose) plus 200 mg/m² melphalan, yielded nearly the same total response rate (CR + PR) as much higher doses of ¹⁶⁶Ho-DOTMP, e.g., 40-50 Gy marrow dose. Also, doses as high as 30-50 Gy of ¹⁵³Sm-EDTMP can be employed with doses of melphalan as high as 200 mg/m² to yield total response rates of >90% without significant urinary tract side effects.

The efficacy of conventional melphalan therapy (i.e., 70-120 mg/m² can also be enhanced by administration of the present complexes, thus improving the outcome for older patients. Therefore, the efficacy of current treatment regimens to treat multiple myeloma, e.g., 140 mg/m² melphalan plus TBI or 200 mg/m² melphalan alone, can be substantially enhanced without substantial increase in side effects, e.g., those due to melphalan and/or TBI used without the complex.

The preferred radionuclide compositions employed in the method of the present invention are capable of delivering a significant portion, preferably greater than about 15%, e.g., about 25-35% of the radioactivity present in the composition to bone tissue while not deleteriously affecting non-target soft tissues. Therefore, for those disease states where the treatment regimen requires bone marrow suppression, the present invention is particularly advantageous since it provides a means of achieving selective reduction in the hemopoietic cell population, without having to resort to external irradiation of the subject, e.g., to TBI, resulting in minimal damage to non-target tissues. The reduction in the

radiation dose delivered to non-target tissues (as compared to the use of TBI alone), provides the opportunity to use the same or increased amounts of conventional chemotherapeutic regimens, particularly non-radioactive antineoplastic ("anti-cancer") agents that per se suppress bone marrow, such as
5 alkylating agents.

It may be possible to completely eliminate the use of targeted radiation or TBI in certain patient populations, such as those under 55 years of age, while retaining equivalent efficacy. It may also be possible to increase the efficacy of regimens in which TBI is desirable, but too hazardous to use, as in older patients
10 (> 55 years of age). However, if it is desirable to employ targeted irradiation or TBI in conjunction with the bone marrow suppression method described herein, for example, in the treatment of leukemia, it can be possible to reduce the radiation dosage used for the total body irradiation and still obtain the same or higher level of reduction of leukemic cells.

15 Preferred radionuclide complexes comprise radionuclides that exhibit half-lives of sufficient length so that they can deliver preselected high doses of radiation after bone-targeting and soft tissue clearance, but which exhibit half-lives sufficiently short so that they decay in a relatively short time to allow safe bone marrow or stem cell transplantation or other therapy. For example, ^{166}Ho and ^{153}Sm have an energetic beta-particle with a long path length. Yet, despite
20 increasing the dose of ^{166}Ho or ^{153}Sm from about 20 Gy to about 50 Gy to the marrow along with moderately high or very high doses of chemotherapy, there has been surprisingly no evidence of delay or difficulty in engraftment of marrow or stem cell transplant due to direct toxicity to the bone marrow space. The rapid
25 radioactive decay and rapid clearance from non-osseous tissues, also unexpectedly permit subsequent use of high dose chemotherapy, since cumulative effects are avoided or lessened. Thus, the present method provides the basis for a potent combination therapy, particularly with respect to cancers that are associated with bone, because additive toxic side effects are readily
30 avoided. At preferred dose of about 650-825 mCi/m², (about 1225-1800 mCi max) which delivers a mean dose of about 15-40 Gy, e.g., about 20-30 Gy, to the bone marrow, cancer patients that are well-hydrated will experience a low

incidence of urinary tract (bladder or kidney) damage, as is discussed in detail below. A representative dose would be about 700-750 mCi/m² (or 1500-2000 mCi max).

In one aspect of the invention, the complex of the macrocyclic
5 aminophosphonic acid, 1,4,7,10-tetraazacyclododecane, and ¹⁶⁶Ho was found to deliver higher doses of radiation to the bone or to adjacent areas than previously thought possible, without undue deleterious side effects. A preferred ratio of DOTMP to ¹⁶⁶Ho is above 3; preferably about 3.5-5, most preferably about 3.5.

Furthermore, it was unexpectedly found that bone marrow can be ablated
10 effectively with a single dose or with closely spaced dosing regimens, further reducing the handler's exposure to radiation. As used herein, the term "single dosage" or "single dose" means that the total dosage of radionuclide complex is administered in one (1) or more doses within a short period of time, *e.g.*, less than about 24 hours. Preferably the doses will be administered within about 12
15 hours, more preferably within about 8 hours. Most preferably the doses will be administered within about 0.1-4 hours. Preferably the dose will be also administered as a single infusion or injection.

Preferably, an effective bone marrow suppressing dose of a radionuclide
aminophosphonic acid complex, such as ¹⁶⁶Ho-DOTMP or ¹⁵³Sm-EDTMP will
20 administer a total dose of 20-60 Gy, preferably about ≤40 Gy and, most preferably, about 20-30 Gy of radiation to the bone/bone marrow of the subject. At about 30% uptake, *e.g.*, for a human subject, total therapy dose to bone marrow is about 500-4000 mCi (about 18.5-148 GBq).

Because the actual percentage of the administered dose of radiation that
25 reaches the bone/bone marrow necessarily varies from subject to subject, the present method also preferably comprises the steps of first administering a dose (the "diagnostic or dosimetry dose") of a radionuclide complex effective to determine the dosage required to subsequently deliver an effective therapy dose or doses, and then determining the percent uptake of the diagnostic or dosimetry
30 dose by the bone of the subject, *e.g.*, via whole body retention measurements. Although a radionuclide other than the intended therapeutic radionuclide can be

used for dosimetry measurements, it is preferable to use the same radionuclide for dosimetry measurements and for therapy.

The administered dosage can, in some cases where patients have relatively low uptake in the skeleton, contain from about 2000 to about 2750
5 megabecquerels (MBq) per kilogram of body weight of said mammal. The most preferred dosage contains from about 2000 to about 2500 megabecquerels per kilogram of body weight of said mammal.

The dosing is preferably accomplished with a radionuclide complex emitting a beta energy of >0.5 MeV and having a radionuclide half-life of less
10 than 5 days, most preferably <3 days, at a beta energy of >1 MeV. Preferred radionuclides include radionuclides selected from the group consisting of ^{153}Sm (half-life 46.3 hr.), ^{90}Y , ^{159}Gd , ^{186}Re , ^{188}Re , and ^{166}Ho (half-life 26.8 hr.) complexed with a bone targeting complexing ligand.

The radionuclide complexes can be administered alone or in combination
15 with adjuvant bioactive agents, that act in conjunction with the localized complex in order to treat diseases, such as disease or pathologies associated with (at or near) mammalian bone (including bone marrow and associated tissue or cells). Such agents include antineoplastic chemotherapeutic agents known to the art. The complex can be delivered at a dose that itself is effective without the
20 use of a chemotherapeutic agent or irradiation from an external source. Such regimens are particularly effective to treat cancers such as leukemia, myeloma, metastatic breast or metastatic prostate cancer, Hodgkin's lymphoma, osteosarcoma, Ewing's sarcoma or Paget's disease.

Following treatment with an amount of the present complexes, and,
25 optionally, with external irradiation, growth factor support, chemotherapy, hormone therapy, or immunosuppressive therapy, the subject's bone marrow can be augmented by blood marrow restoration, or regenerated, as by transplantation with purged autologous or matched allogeneic bone marrow (including peripheral blood stem cells), and/or by treatment with bone marrow-stimulating
30 agents.

The preferred chelating agents useful for practicing the present invention are polyaminophosphonic acid chelators, such as, for example,

- ethylenediaminetetramethylenephosphonic acid (EDTMP),
 diethylenetriaminepentamethylenephosphonic acid (DTPMP),
 hydroxyethylethylenediaminetrimethylenephosphonic acid (HEEDTMP),
 nitrilotrimethylenephosphonic acid (NTMP), 1,4,7,10-
- 5 tetraazacyclododecanetetramethylenephosphonic acid (DOTMP), tris(2-aminoethyl)aminehexamethylenephosphonic acid (TTHMP), 1-carboxyethylenediamine-tetramethylenephosphonic acid (CEDTMP), hydroxyethylidene diphosphonate (HEDP), bis(aminoethylpiperazine)tetramethylenephosphonic acid (AEPTMP), N-
- 10 methylethylenediaminetrimethylenephosphonic acid (MEDTMP), N-isopropylethylenediaminetriemthylenephosphonic acid (IEDTMP), N-benzylethylenediaminetrimethylenephosphonic acid (BzEDTMP), methylene diphosphonate, hydroxymethylene diphosphonate, ethane-1-hydroxy-1,1-diphosphonic acid, and the like. Other useful chelating agents for radionuclides
- 15 are generally disclosed in U.S. Patent Nos. 5,059,412, 5,066,478, 5,300,279 and 4,897,254.

Preferred macrocyclic aminophosphonic acids are of the structure:

- 20 wherein substituents A, B, C, and D are independently selected from hydrogen, hydrocarbon radicals having from 1-8 carbon atoms,

and physiologically acceptable salts of the acid radicals wherein X and Y are independently selected from the group consisting of hydrogen, hydroxyl, carboxyl, phosphonic, and hydrocarbon radicals having from 1-8 carbon atoms and physiologically acceptable salts of the acid radicals, and n is 1-3 with the proviso that when $n > 1$, each X and Y may be the same as or different from the X and Y of any other carbon atom; XN and YN are independently hydrogen, methyl, or ethyl radicals, and nN is 2 or 3, with the proviso that at least two of said nitrogen substituents is a phosphorus containing group, i.e., wherein N and P are connected by alkylene or substituted alkylene.

10 A more preferred macrocyclic aminophosphonic acid ligand is 1,4,7,10-tetraazacyclododecanetetramethylenephosphonic acid (DOTMP). See, *e.g.*, U.S. Patent Nos. 4,973,333 and 5,714,604. Another preferred aliphatic ligand is EDTMP. See, *e.g.*, U.S. Patent Nos. 4,853,209 and 4,898,724.

15 The present method can also be employed to treat pathologies other than cancer associated with (at or near) mammalian bone, that can be ameliorated by partial bone marrow suppression or by complete bone marrow ablation followed by bone marrow transplantation. The treatment can be accomplished by delivering i.e., 250-3000 megabecquerels per kg of body weight of the complex to the subject to be treated. Such pathologies include, but are not limited to, immunological disorders such as autoimmune diseases, *e.g.*, Crohn's disease, 20 rheumatoid arthritis or multiple sclerosis; metabolic diseases, such as osteoporosis or osteopenia; infections and infectious disease such as tuberculosis or blastomycoses, inflammatory diseases such as osteomyelitis or Paget's disease; hematopoietic disorders, and conditions treatable with stem cell transplantation, with or without gene therapy, that utilize bone marrow ablation, 25 such as sickle cell anemia and lysosomal and peroxisomal storage diseases.

 The present invention also provides novel liquid compositions, preferably aqueous compositions, comprising ^{166}Ho -DOTMP or ^{153}Sm -EDTMP combined with an effective stabilizing amount of ascorbic acid, gentisic acid, or other 30 radio-stable stabilizing agent buffered to pH 7-8, as well as methods for preparing the compositions. The ascorbic acid, gentisic acid, and the like, maintain the radionuclide complex stability and reduces the amount of free

radionuclide delivered *in vivo*. For example, ascorbic acid or gentisic acid may be present in the unit dosage forms useful in the practice of the present invention at about 35-75 mg/ml of composition. Stabilization unexpectedly inhibits radiolytic degradation of the complexes, i.e., so high (300 mCi/ml (12 GBq/ml)) levels of ^{166}Ho -DOTMP or ^{153}Sm -EDTMP can be maintained in the dosage forms, and thus allows distribution to hospitals at high levels of purity, with high levels of radionuclide complex.

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 is a graphical representation of the uptake of ^{166}Ho -DOTMP in bones and non-target organs.

Figures 2-4 are graphical representations of a comparison of the uptake of ^{166}Ho -DOTMP in bones and non-target organs when using a stabilizer.

DETAILED DESCRIPTION OF THE INVENTION

As used herein, the term "mammal" means a warm blooded mammal, including humans, and is meant to encompass mammals in need of bone marrow suppression, especially humans; thus in some instances the term "patient" or "subject" is alternatively used for mammal.

The term "disease" includes pathologies and deleterious conditions, such as inflammatory responses, cancer, autoimmune, and genetic disorders.

The term "bone marrow restoration" includes partial or complete regeneration or augmentation of the bone marrow by marrow transplantation or hematopoietic stem cell transplantation and/or stimulation of bone marrow regeneration by administration of growth factors such as cytokines, glycoproteins and the like.

As used herein, the term "bone marrow transplant (BMT)" includes autologous, allogenic, xenogeneic marrow transplantation and stem cell transplantation.

The term "bone marrow suppression" refers to partial or essentially total eradication ("ablation" or "myeloablation") of the bone marrow, in particular a temporary or permanent reduction of the hemopoietic stem cell population.

A sub-ablative therapy is one that does not completely eradicate bone marrow, e.g., the marrow may recover, particularly if hematopoietic cell growth factors are administered.

As used herein, the term that external irradiation (targeted or TBI) is not used "in conjunction with" the radionuclide complex and, optionally, chemotherapy, is intended to mean that external irradiation is not employed as part of the same treatment protocol. For example, a patient could have received external radiation treatment as part of a previous treatment protocol and still be considered not to have received external radiation "in conjunction with" treatment with the radionuclide complex. Thus, the term "inconjunction with" is intended to mean administration as part of the same protocol radionuclide complex, in order to accomplish the recited therapeutic effect, e.g., bone marrow suppression.

As used herein, the term "substantial" when used with respect to the side effects of chemotherapy or radiation therapy is to be understood by reference to the art-recognized definitions and scales employed in the working examples.

As used herein, the term "high dose" refers to a dose that is in the upper range of the dose used in conventional therapy to treat a particular pathology, as recognized by the art. As defined in Example 10, this can include the MTD $\pm 10\%$. The dose range and highest typical dose for certain chemotherapeutic agents is given herein below for illustration.

The present invention is directed to compositions and methods for suppressing bone marrow and/or treating a disease in or near the bone or bone marrow that is ameliorated by said suppression. The present invention has significant benefits in that it permits rapid and selective bone marrow suppression (the bone marrow can be suppressed with only minimal damage to non-target soft tissues, such as, for example, lung, liver, stomach, mucosal linings and the like) without the need for sustained exposure to radiation or for exposure to a large, > about 15-20:1, molar ratio of chelating agent to radionuclide. The complexes of the invention can also be administered prophylatically or in an adjuvant setting with little evidence of disease but

likelihood of recurrence from minimal disease presence, e.g., to minimize the probability of metastases of established cancer.

As will be more fully discussed later herein, the properties of the radionuclide, and of the radionuclide aminophosphonic acid complex are important considerations in determining which radionuclide composition should be employed for any particular treatment. For the purpose of convenience, the radionuclide aminophosphonic acid compositions will frequently be referred to as "radionuclide complexes or compositions" and the aminophosphonic acid derivative referred to as the "ligand," "chelator," or "chelating agent". The term "complexes" or "compositions" includes both the free compounds and the pharmaceutically acceptable salts thereof.

Radionuclides

It is important that the half-life of the complexed radionuclides be sufficiently long to allow for localization and delivery of the complex in the bone tissue via binding to chelator while still retaining sufficient radioactivity to accomplish essentially total bone marrow suppression or eradication. The half-life also should be relatively short, so that after bone marrow irradiation is achieved, it is possible to proceed with bone marrow or stem cell transplantation with minimal delay prior to transplant, and in order to enhance the prospects of bone marrow engraftment and patient recovery. Generally, it is preferred to use a radionuclide complex that results in rapid biolocalization of the radionuclide in the bone tissue so as to achieve rapid onset of bone marrow irradiation. It is also beneficial to use a radionuclide having sufficient beta energy, such that substantially all bone marrow cells receive a toxic irradiation from the targeted bone surfaces.

For example, radionuclides useful for bone marrow ablation can exhibit beta energy >0.5 MeV, preferably >1 MeV with an effective half-life of about <5 days, preferably <3 days. Certain radionuclides such as Sr-89 have been demonstrated, when selectively deposited in bone, to suppress bone marrow. [See, for example, Y. Shibata *et al.*, J. Leukocyte Biol., **38**, 659 (1985).] However, this compound is not clinically useful for this purpose since the long

half-life of Sr-89 (50 days) prevents transplantation of the new marrow for an unacceptable period of time. Radionuclides useful in the method and compositions of this invention are Arsenic-77 (^{77}As), Molybdenum-99 (^{99}Mo), Rhodium-105 (^{105}Rh), Lutetium-177 (^{177}Lu), Cadmium-115 (^{115}Cd), Antimony-122 (^{122}Sb), Promethium-149 (^{149}Pr), Osmium-193 (^{193}Os), Gold-198 (^{198}Au), Thorium-200 (^{200}Th); preferably Samarium-153 (^{153}Sm), Yttrium-90 (^{90}Y), Gadolinium-159 (^{159}Gd), Rhenium-186 (^{186}Re), Rhenium-188 (^{188}Re), and Holmium-166 (^{166}Ho). Especially preferred is ^{166}Ho , which emits high energy beta particles and gamma radiation (80 KeV, 6.0%) useful for imaging and exhibits a half-life of 26.8 hr.

The respective radionuclides can be obtained using procedures well known in the art. Typically, the desired radionuclide can be prepared by irradiating an appropriate target, such as a metal, metal oxide, or salt. Another method of obtaining radionuclides is by bombarding nuclides with particles in a linear accelerator or cyclotron. Yet another way of obtaining radionuclides is to isolate them from fission product mixtures. The method of obtaining the radionuclide is not critical.

^{153}Sm is produced in high yield and purity by neutron irradiation of isotopically enriched $^{152}\text{Sm}_2\text{O}_3$. It emits both medium energy beta particles and a gamma photon and has a physical half-life of 46.3 hours. ^{153}Sm has average and maximum beta particle ranges in water of 0.5 mm and 3.0 mm respectively.

Chelating Agents

Aminophosphonic acids, particularly macrocyclic aminophosphonic acids, are the ligands of choice as chelators for the radionuclides useful in the present methods. These compounds can be prepared by a number of known synthetic techniques. Generally, a compound containing at least one reactive amine hydrogen is reacted with a carbonyl compound (aldehyde or ketone) and a phosphorous acid or appropriate derivative thereof.

Methods for carboxyalkylating macrocyclic amines to give amine derivatives containing a carboxylalkyl group are disclosed in U.S. Pat. No. 3,726,912. Methods to prepare alkylphosphonic acid amines and

hydroxyalkylamines are disclosed in U.S. Pat. No. 3,398,198. See also, U.S. Pat. No. 5,066,478 and 5,300,279.

5 The amine precursor (1,4,7,10-tetraazacyclododecane) employed in making certain of the macrocyclic aminophosphonic acids is a commercially available material. The preparation of the macrocyclic aminophosphonic ligand of this invention can also be found U.S. Patent No. 5,059,412 entitled "Macrocyclic Aminophosphonic Acid Treatment of Calcific Tumors"; by Simon et al., the disclosure of which is hereby incorporated by reference.

The preparation of these ligands have been described in several U.S. Patents such as, U.S. Patent 4,973,333, U.S. Patent 4,882,142, U.S. Patent 4,853,209, U.S. Patent 4,898,724, U.S. Patent 4,897,254, U.S. Patent 5,587,451, U.S. Patent 5,714,604, U.S. Patent 5,064,633, U.S. Patent 5,587,451, U.S. Patent 5,066,478, U.S. Patent 5,300,279, U.S. Patent 5,059,412, and U.S. Patent 5,064,633. The preferred ligands useful for practicing the present invention are selected from the group consisting of ethylenediaminetetramethylenephosphonic acid (EDTMP), diethylenetriaminepentamethylenephosphonic acid (DTPMP), hydroxyethylethylenediaminetrimethylenephosphonic acid (HEEDTMP), nitrilotrimethylenephosphonic acid (NTMP), 1,4,7,10-tetraazacyclododecanetetramethylenephosphonic acid (DOTMP), tris(2-aminoethyl)aminehexamethylenephosphonic acid (TTHMP), methylene diphosphonate, hydroxymethylene diphosphonate, hydroxyethylidene diphosphonate (HEDP); and ethane-1-hydroxy-1,1-diphosphonic acid. Preferred ligands are macrocyclic aminophosphonic acid ligands of which 1,4,7,10-tetraazacyclododecanetetramethylenephosphonic acid (DOTMP) is an example.

25 The present invention includes the use of the bone marrow suppressing method and composition in combination with other drugs and/or radiation sources.

Radionuclide Complexes

Radionuclide complexes suitable for use in the present invention must have particular properties to be suitable as therapeutic agents. The radionuclide complex must be taken up preferentially by bone so that it is possible to deliver a bone marrow suppressing dose of radiation to the bone marrow with minimal

exposure to other tissues such as lung, liver, bladder or kidneys. The radionuclide complex also should be rapidly taken up by bone and rapidly cleared from the blood, thereby further reducing exposure to non-target tissues.

The radionuclide and ligand can be combined under any conditions that
5 allow the two to form a complex. Generally, mixing in water at a controlled pH (the choice of pH is dependent upon the choice of ligand and radionuclide) is all that is required. The complex is formed by chelation of the radionuclide by an electron donor group or groups that results in a relatively stable radionuclide complex, e.g., stable to the disassociation of the radionuclide from the ligand.
10 For example, ^{166}Ho -DOTMP is formed by adding a ^{166}Ho salt, such as the chloride or nitrate in aqueous HCl (0.1-1N), to a sterile, evacuated vial containing at least 3 equivalents of DOTMP in aqueous base (KOH, NaOH and the like). After stirring at a pH = 10.5, the pH is then adjusted to 7-8 by adding phosphate buffer and a stabilizing agent such as ascorbic acid. Complexation of
15 >99% is achieved.

For the purpose of the present invention, bone marrow suppressing radionuclide compositions described herein and physiologically acceptable salts thereof are considered equivalent. Physiologically acceptable salts refer to the acid addition salts of those bases which will form a salt with at least one acid
20 group of the ligand or ligands employed and which will not cause significant adverse physiological effects when administered as described herein. Suitable bases include, for example, the alkali metal and alkaline earth metal hydroxides, carbonates, and bicarbonates such as, for example, sodium hydroxide, potassium hydroxide, calcium hydroxide, potassium carbonate, sodium bicarbonate,
25 magnesium carbonate and the like, amine hydroxides, carbonates, and bicarbonates such as, for example, ammonium hydroxide, ammonium carbonate, and the like, or primary secondary and tertiary amine hydroxides, carbonates, and bicarbonates such as, for example, trimethyl ammonium carbonate and the like. Physiologically acceptable salts can be prepared by treating the macrocyclic
30 aminophosphonic acid with an appropriate base.

The macrocyclic aminophosphonic acid complexes when formed at approximately a ligand to metal molar ratio of 1:1 to 20:1 give biodistributions

that are consistent with those exhibited by known agents that are bone-specific. The preferred bone marrow suppressing radionuclide composition utilizes ^{166}Ho with DOTMP. Preferably, molar ratios of DOTMP to ^{166}Ho are above 3, e.g., 3.5-5:1. The most preferred ratio is about 3.5:1. Such ratio provides adequate complexation of the radionuclide while compensating for radiolysis of the ligand. Lower ratios of DOTMP to ^{166}Ho are unstable *in vivo* and not therapeutically effective. By contrast, other acyclic aminophosphonic acid complexes can result in substantial localization of radioactivity in soft tissue (e.g., liver) if large excess amounts of ligand are not used. Large excesses of ligand are undesirable since uncomplexed ligand may be toxic to the patient or may result in cardiac arrest or hypocalcemic convulsions. In addition, the macrocyclic aminophosphonic acid ligands are useful when large amounts of metal are required (*i.e.* for metals that have a low specific activity). In this case, the macrocyclic aminophosphonic acid ligands have the ability to deposit more tolerable doses of radioactivity in the bone than is possible when using non-cyclic aminophosphonic acid ligands.

Stabilizing Agents

A pharmaceutically acceptable means of protecting the radionuclide complex from radiolytic decay of the chelator is highly preferred. Preferred radioprotectants of the present invention are radio-stable anti-oxidants, compounds that either reduce the number or the activity of oxidizing radicals. Exemplary radioprotectants that can be employed in the practice of the present invention are ascorbic acid, gentisic acid, nicotinic acid, ascorbyl palmitate, HOP(:O) H₂, monthioglycerol, sodium formaldehyde sulfoxylate, Na₂S₂O₅, Na₂S₂O₃, SO₂, or a reducing agent combined with BHA, BHT, pyrogallate or tocopherol and the like. Ascorbic acid is the preferred radioprotectant for use in the practice of the present invention, and can be used at about 35-75 mg/mL of liquid composition. This concentration of ascorbate can provide a solution of ^{166}Ho -DOTMP that is stable, e.g., therapeutically useful, for at least 72 hours, at ambient conditions, e.g., unfrozen.

The formulations of the present invention are in the solid or preferably liquid form containing the active radionuclide complexed with the ligand. These formulations can be in kit form such that the chelator and radionuclide are mixed at the appropriate time prior to use in a suitable liquid carrier with the
5 radioprotectant. Whether premixed or as a kit, the formulations usually require a pharmaceutically acceptable carrier, such as water.

Pharmaceutical Dosage Forms

The pharmaceutical dosage forms suitable for injection or infusion can
10 include sterile solutions, dispersions, emulsions, or microemulsions, comprising the active ingredient which are adapted for the extemporaneous preparation of sterile injectable or infusible solutions or dispersions, optionally encapsulated in protective matrices such as nanoparticles or microparticles. In all cases, the ultimate dosage form must be sterile, fluid and stable under the conditions of
15 manufacture and storage. The liquid carrier or vehicle can be a solvent or liquid dispersion medium comprising, for example, water, ethanol, a polyol (for example, glycerol, propylene glycol, liquid polyethylene glycols, and the like), DMSO, and suitable mixtures thereof. In many cases, it will be preferable to include isotonic agents, for example, sugars, buffers or sodium chloride. In
20 some cases, it will be advisable to provide the unit dosage form wherein the vehicle is frozen after formulation.

Injectable suspensions as compositions of the present invention require a liquid suspending medium, with or without adjuvants, as a carrier. The suspending medium can be, for example, aqueous polyvinylpyrrolidone, inert
25 oils such as vegetable oils or highly refined mineral oils, or aqueous carboxymethylcellulose solutions. If necessary to keep the complex in suspension, suitable physiologically acceptable adjuvants can be chosen from among thickeners such as, for example, carboxymethylcellulose, polyvinylpyrrolidone, gelatin, and the alginates. Many surfactants are also useful
30 as suspending agents, for example, lecithin, alkylphenol, polyethylene oxide adducts, naphthalenesulfonates, alkylbenzenesulfonates, and the polyoxyethylene sorbitan esters. Many substances that effect the hydrophobicity, density, and

surface tension of the liquid suspension medium can assist in making injectable suspensions in individual cases. For example, silicone antifoams, sorbitol, and sugars are all useful suspending agents.

5 Dosages of the Radionuclide Complexes

The "bone-marrow suppressing amount" or other effective therapeutic amount of radionuclide composition administered to achieve bone marrow suppression will vary according to factors such as the age, weight and health of the patient, the disease state being treated, the treatment regimen selected, as well as the nature of the particular radionuclide composition to be administered. For example, less activity will be needed for radionuclides with longer half lives. The energy of the emissions will also be a factor in determining the amount of activity necessary. Preferably, a total dose of about 20-60 Gy, most preferably about 30-60 Gy, e.g., 40-50 Gy of radiation will be delivered to bone marrow via bone localization.

The radiation exposure is reported using the Grey scale (Gy) and is typically determined using a diagnostic dose of about 1200-2000 MBq (about 30 mCi to about 50 mCi) of the radionuclide/ligand. Determination of the doses of radiation delivered by the present complexes can be determined in accord with the methodologies of M. Bardies et al., Physics in Medicine and Biology, **41**, 1941 (1996); J. Bayouth, Radiation Physics, University of Texas - Houston Graduate School of Biomedical Science: 111 (1993); A. H. Beddoe et al., Physics in Medicine & Biology, **21**, 589 (1976); R. Bigler et al., Health Physics, **31**, 213 (1976); R. Champlin et al., Semin. Hematol, **24**, 55 (1987); R. E. Champlin et al., Cancer Treatment Reports, **68**, 145 (1984); K. Eckerman et al., Journal of Nuclear Medicine, **35**, 112P (1994); T. E. Hiu et al., Proceedings of International Conference on Radiation Dosimetry and Safety, Taipei, Taiwan, American Nuclear Society (1987); I.C.R.P Report of the task group on reference man: anatomical, physiological and metabolic characteristics. New York, Pergamon Press (1973); R. L. Loevinger et al., MIRD Primer for Absorbed Dose Calculations, New York, Society of Nuclear Medicine (1991); F. W. Spiers et

al., British Journal of Radiology, **54**, 500 (1981); S. R. Thomas et al., J. Nucl. Med., **35**, 73 (1994)]," Journal of Nuclear Medicine, **33**, 783 (1992).

Table 1 indicates the dosage levels achieved at various levels of skeletal uptake of the radionuclide.

5

TABLE 1

DOSAGE LEVELS AT PERCENT SKELETAL UPTAKE			
Dose Level vs. Dose Required in MBq/kg¹			
Dose Level	15% Uptake	30% Uptake	45% Uptake
20 Gy	1110	518	370
30 Gy	1665	777	555
40 Gy	2220	1036	740
50 Gy	2775	1295	925

The radiation amounts herein are reported in megabecquerels (MBq), Gy, or in mCi, e.g., as mCi/m². The conversion between mCi and MBq for an average patient is illustrated below:

10

$$22.0 \text{ mCi/kg} \times 70 \text{ kg} \times 37 \text{ MBq/mCi} = 56,980 \text{ MBq (or 814 MBq/kg)}.$$

wherein 70 kg is used as an average patient weight. Herein both terms have been used. A becquerel is 1 disintegration per minute (dpm).

15

For internal dosimetry for radiopharmaceuticals, such as ¹⁶⁶Ho-DOTMP, the mean absorbed dose to a target tissue from activity within a source organ can be calculated using the general method defined by the Medical Internal Radiation Dose (MIRD) Committee of the Society of Nuclear Medicine (R. Loevinger et al. (1991) MIRD Primer for Absorbed Dose Calculations, New York, Soc. Nucl. Med.).

20

The MIRD formalism simplifies this relationship for a radiation source (h) irradiating a target (k) to:

$$\bar{D} = \tilde{A}_h \cdot S_{(k \leftarrow h)}$$

25 Where:

$$\bar{D} = \text{Mean absorbed dose to the target organ of mass } m_k$$

¹ Average skeletal uptake in patients is about 30%

\tilde{A}_h = Cumulative Activity, the total number of radioactive transitions within the source organ

$S_{(k \leftarrow h)}$ = S-value of source h irradiating target k
 $= \sum \Phi_{i(k \leftarrow h)} \bullet \Delta i$

5 where:

Δi = amount of energy released per transition per specific radiation

Φ = specific absorbed fraction

and:

$$\Phi(k \leftarrow h) = \frac{\phi_i(k \leftarrow h)}{m_k}$$

10

where:

$\phi_i(k \leftarrow h)$ = absorbed fraction, the fraction of energy emitted from source organ absorbed in target organ for specific radiation,
 15 i

m_k = mass of target

S-values for ^{166}Ho were provided by Michael Stabin, Ph.D, while at Oak Ridge Associated Universities. These S-values were generated for the Standard
 20 Man Adult Male Phantom as defined by Cristy and Eckerman (M. Cristy, et al., Specific Absorbed Fractions of Energy at Various Ages from Internal Photon Sources, ORNL/TM-8381 V1-V7, Oak Ridge Nat'l Lab., Oak Ridge, TN) using the revised bone and bone marrow model included in the software package, MIRDOSE 3.1.

25 In the case where activity is measured as a fraction of the total injected, rather than in mCi, as in this protocol, the value of the cumulative activity in the skeleton, \tilde{A} , is equivalent to the residence time. Therefore:

$D = RT \times S$, where D is the dose to target organ per unit activity (cGy/mCi).

Dose To Bone Marrow

Ho-166-DOTMP is primarily a bone surface-seeking agent. ¹⁶⁶Ho is a beta-emitting radionuclide with 60% of the energy deposited over 1.95 to 2 mm in tissue, and a maximum pathlength of 8.7 mm. Thus, the energy deposition will take place mostly in the bone and proximal bone marrow.

The average dose to the bone marrow from the tracer dose is estimated from whole body counting. Counting the photons in the patient at several time points indicates the amount of ¹⁶⁶Ho-DOTMP retention in the patient. Based on gamma camera imaging, the activity that is not excreted within 18 hours is known to be retained in the skeleton. The following steps will be taken to derive the skeletal RT:

a) Geometric mean whole body counts from gamma camera images will be corrected for stability of the counting system using the calibration standard, and the fraction injected dose (*f*) will be determined for each time point and used to obtain a whole body time activity curve.

b) The fraction remaining within the total body at any time point *f*(*t*) will be calculated as follows:

$$f(t) = N_t/N_o \times T_o/T_t \times S_o/S_t,$$

Where:

N_o = background subtracted, geometric mean counts in initial measurement,

N_t = background-subtracted geometric mean counts at time *t*,

T_o = acquisition time for initial measurement,

T_t = acquisition time for measurement at time *t*

S_o = counts per mCi in standard at initial measurement

S_t = counts per mCi in standard at time *t*

c) Time-activity curves of the whole body effective and decay corrected data will be derived.

d) From a mono-exponential fit of the fraction of the initial dose remaining in the patient at the last 3 time points, an estimate of

the fraction of initial activity (f) localizing in the skeleton and the rate of skeletal clearance ($t_{1/2 \text{ effective}}$) will be derived.

- e) The skeletal $f \times T_e$ will be derived.
- f) The skeletal residence time (RT), which is used for estimating the dose per unit radioactivity injected (cGy per mCi), will be calculated using this equation:

$$\text{Skeletal RT} = 1.44 \cdot f \cdot T_e$$

If the skeletal RT is < 5.76 hours, the patient is not eligible for therapy.

- g) It is assumed that the DOTMP localizes equally on any bone surface. However, because the red marrow is in close proximity with the trabecular bone, the activity on the trabecular surface is assumed to be the primary source irradiating marrow. For the marrow dose estimate, the total skeletal RT is assumed to be distributed between trabecular and cortical bone surfaces. Based on estimates of surface area of the bone, the trabecular bone surface accounts for 62% of the total bone surface (ICRP (1995). Pub. 70. Basic Anatomical and Physiological Data for Use in Radiological Protection: The Skeleton. New York, Pengamon Press). Thus 0.62 of the above skeletal residence time is apportioned into the trabecular bone surface to estimate the dose to marrow.

In this case, dose marrow is estimated using the following equation:

$$\overline{D} = RT \cdot S(\text{BM} \leftarrow \text{TB})$$

where:

\overline{D} = Mean absorbed dose to the *marrow* (BM) of mass m

RT = Total number of radioactive transitions within the *trabecular bone* (TB) (this value is 0.62 of the value for whole skeleton)

$S = S_{(BM \leftarrow TB \text{ surface})}$, the S-value for trabecular bone surfaces irradiating adjacent bone marrow

$$= \sum \Phi_i(BM \leftarrow TB \text{ surface}) \bullet \Delta i$$

- 5 h) For all males and females, irrespective of weight, the adult trabecular bone surfaces to red marrow S-value of 0.373 cGy/mCi-hour will be used, corrected for marrow mass according to body surface area (BSA). The S value for each patient will be adjusted according to body surface using a ratio of 1.8 (adult MIRD model BSA) to the patient's BSA.
- 10 i) Similar calculations to that described above will be done for the small contribution of activity from the cortical bone surface and from the remainder of the body irradiating the marrow, using appropriate RT and S values. These doses will be added to the dose to the marrow from the trabecular bone to estimate the total
- 15 marrow dose. This additional contribution accounts for less than 5% of the marrow dose.

Because of the rapid clearance of non-targeted ^{166}Ho -DOTMP through the urinary system, the bladder and kidneys are exposed to higher doses of radioactivity than the other soft tissues and require special attention.

- 20 A physiological dosimetry model for estimating the radiation absorbed dose to the bladder wall, the MIRD Dynamic Bladder Model, Revised (J. Nucl. Med., 40, 1025-1235 (1999)) will be used. This model was modified to consider aggressive hydration and bladder irrigation. Assumptions for this model include the flow rate into the bladder, which is assumed to be 8 ml/minute (a
- 25 combination of high urine flow from aggressive hydration and irrigation fluid), and a residual volume of 30 ml. The activity entering the bladder is derived from a bi-exponential fit of the whole body count data, as all activity excreted is via the urinary system.

- 30 The kidney dose will be estimated using the ICRP 53 mathematical model for kidney dose (ICRP (1987), Publ. 53. Radiation Dose To Patients From Radiopharmaceuticals, New York, Pengamon). The residence time for this model is based on considering urine flow through the kidneys as the primary

contributing factor to the kidney dose. The amount of activity passing through the kidneys is determined from the whole body clearance from gamma camera counting, and the transit time of the radioactivity in the kidney was determined from prior work assessing the time to peak kidney activity. Three minutes was
5 the assumption chosen, which is a conservative estimate for the first six hours when the patients are being hydrated, during which 80% of the dose in the urine is excreted. The RT in the kidney is determined by integrating this information.

The adult S-values for the kidneys will be used for all patients, corrected for kidney mass. The mass of the kidney will be determined by ultrasound when
10 assessing patient eligibility. The length, width, and thickness of the kidneys will be measured. Kidney volume (mass) will be estimated from the formula:

$$V=L * W * T (\pi/6)$$

from T. B. Jones et al., J. Ultrasound Med, 2, 1751 (1983).

Data will also be obtained directly from 5 static posterior kidney images
15 to derive a residence time for estimating the kidney radiation absorbed dose.

Patients will be imaged three times for 5 minutes on the day of injection and twice for 10 minutes on the second day.

Counts in three windows will be corrected for background, scatter and attenuation. The scatter-subtracted standard counts will be used as a calibration
20 factor.

Attenuation will be estimated using the effective point source method, the depth based on the ultrasound measurements.

Time activity curves will be created to derive the cumulative activity in the kidney to determine the residence time.

25 For the estimate of doses to other non-source organs, the remainder body residence time will be derived from the whole body data. To avoid estimating dose from the same activity twice, remainder body S-values will be derived according to the 1991 MIRD recommendations. This involves removing a fraction of the S-value from source organs to target organs depending on the
30 mass of the organ. Organs included in this subtraction are trabecular bone, cortical bone, bladder and kidney, as described below.

$$S(r_k \leftarrow RB) = S(r_k \leftarrow TB) \left(\frac{m_{TB}}{m_{RB}} \right) - \sum S(r_k \leftarrow r_h) \left(\frac{m_h}{m_{RB}} \right)$$

Where:

r_k = target organ

r_h = source organ

5 m_{TB} = mass of the total body

m_{RB} = mass of the remainder of the body

m_h = mass of source organ h

The dose to the non-source organs will be determined by multiplying the
10 remainder body residence time by the respective S-values. For all organs other
than those discussed specifically above, the adult S-values will be used for all
patients >63 Kg, and the adult female S-values for all patients less than 63 Kg.

The results of patients treated with 20 30 and 40 Gy with 140 mg/mL and
200 mg/m² are given in Example 11.

15 As discussed above, and exemplified below, the administered dose of
radiation can be calculated by pre-administration of a diagnostic dose of a
radionuclide complex. Depending on the percent bone uptake of a given
radionuclide complex by a given subject, which is generally in the range of about
15 to about 45%, the range of activity per administered dose can generally be
20 from about 250 to about 3000 megabecquerels per kilogram of body weight of
said mammal. If uptake is low, or if a very high dose is desired, a dose of from
about 750 to about 2500 megabecquerels per kilogram of body weight of said
mammal, or from about 1000 to about 2000 megabecquerels per kilogram of
body weight of said mammal may be preferred. The effective amount used to
25 obtain bone marrow suppression will typically be administered, generally by
administration into the bloodstream, in a single or multi-dose infusion.

Bone Marrow Transplantation and Restoration

The general techniques of autologous or allogeneic bone marrow
30 transplantation or "rescue" are well known in the art, see for example, F. R.
Appelbaum et al., "The Role of Marrow Transplantation in the Treatment of

Leukemia", (pp. 229-262), C. D. Bloomfield (ed.), Chronic and Acute Leukemias in Adults, Martinus Nijhoff Publishers, Boston (1985); E. D. Thomas, "Clinical Trials with Bone Marrow Transplantation", (pp. 239-253), Clinical Trials in Cancer Medicine, Academic Press, Inc. (1985); E. D. Thomas, 5 Journal of Clinical Oncology, **1**, 517 (1983); E. D. Thomas et al., Annals New York Academy of Sciences, **445**, 417 (1985).

Under general or spinal anesthesia and using standard marrow aspiration needles, multiple aspirates are performed from the anterior and posterior iliac crests and, occasionally, the sternum of the donor. The marrow is placed in 10 heparinized tissue culture media and then, using metal screens, filtered to remove bony spicules and fat globules and to create a monocellular suspension. At the time of desired administration of the bone marrow, the marrow is infused intravenously, following which the marrow stem cells migrate to the marrow space, proliferate, and eventually restore normal hematopoiesis and immune 15 function. It is preferable to give as many bone marrow cells as possible to enhance the prospects of marrow engraftment. Following allogeneic transplant the patient usually receives some form of immunosuppression, such as by administration of methotrexate or cyclosporine, in an attempt to prevent or at least modify graft-versus-host disease.

20 A more preferred method for retrieving bone marrow stem cells involves harvesting these cells from the peripheral blood. The purity of stem cells is enhanced by techniques such as negative selection with antibodies specific for hematopoietic cell markers. In order to increase the concentration of stem cells in the blood, patients are pretreated with chemotherapy, or pretreated with a 25 colony stimulating factor such as G-CSF, GM-CSF, or SC-CSF. These cytokines are also used after TBI and marrow or stem cell transplant to enhance engraftment.

The use of high dose chemotherapy followed by stem cell support has become one of the most attractive therapeutic approaches in multiple myeloma 30 since, in relation to conventional chemotherapy, it increases the number of complete remissions (CR), duration of event free survival (EFS) and probably, overall survival (OS). In this setting of high dose chemotherapy, the use of

¹⁶⁶Ho-DOTMP to suppress (ablate) the marrow in order to eradicate the malignant cells more effectively, requires stem cell support. With total marrow ablation using ¹⁶⁶Ho-DOTMP a stem cell rescue is required using autologous stem cells collected prior to therapy.

5 Preferably, autologous stem cells or bone marrow cells are purged of cancerous plasma cells or tumor cells by methods known to the art, such as binding the plasma cells with antibody-toxin conjugates or CD34⁺ selection for stem cell enrichment. The ability to give back the patients stem cells post ablative therapy helps to regenerate the host hematopoiesis and thus protect the
10 patient from potentially life-threatening complications. In the case of multiple myeloma patients treated with the present method, e.g., high dose melphalan and 20-50 Gy of radiation to bone marrow from ¹⁶⁶Ho-DOTMP, the high efficiency of bone marrow suppression effectively increases the negative effect of residual cancer cells in autologous marrow. Therefore, purging autologous cells can
15 improve the outcome for such patients.

Treatment of Cancer

A. Chemotherapeutic Agents

20 In the treatment of a patient having a cancer such as leukemia or multiple myeloma, the use of the radionuclide compositions described herein can reduce or eliminate the neoplastic cell population in the bone marrow. The aminophosphonate ligands also lead to enhanced uptake of the radionuclide by neoplastic bone lesions, which represent areas of active bone matrix turnover. However, it will usually be necessary to administer one or more
25 chemotherapeutic agents, to destroy the undesirable cells in locations other than the bone marrow or in sanctuaries within the bone marrow, or to add to the effects of the radiation. The efficacy of cancer elimination can be enhanced by the use of protein synthesis inhibitors, in order to inhibit repair of damaged DNA in the cancer cells.

30 Chemotherapeutic antineoplastic ("anti-cancer") agents that are useful in practicing the present invention include but are not limited to doxorubicin, fludarabine, ifosfamide, thiotepa, melphalan (L-phenylalanine, 4-[bis(2-

chloroethyl)amino]-), methotrexate, mitoxantrone, estramustine, bleomycin, vinblastine, taxanes, thalidomide, etoposide, tamoxifen (anti-estrogens) (10-20 mg 2X daily for breast cancer), paclitaxel, vincristine, dexamethasone, busulfan, cyclophosphamide, bischloroethyl nitrosourea, cytosine arabinoside, 6-
5 thioguanine, organoplatinum-based agents and analogs thereof. Preferred chemotherapeutic agents that are useful in practicing the present invention, particularly with respect to metastatic breast cancer are doxorubicin, thiotepa, melphalan, methotrexate, bleomycin, vinblastine, taxol, taxanes, tamoxifen, busulfan and analogs thereof. Preferred chemotherapeutic agents, particularly
10 for the treatment of metastatic prostate cancer include mitoxantrone, estramustine, adriamycin and taxanes. Hormone (e.g., anti-androgen) treatment can also be employed to inhibit the spread of prostate cancer, as can use of non-steroidal anti-inflammatory agents such as etodolac.

Preferred chemotherapeutic agents for treatment of multiple myeloma
15 include melphalan, thalidomide, vincristine, doxorubicin, dexamethasone and doxorubicin.

The present method is particularly advantageous in that it can be used with chemotherapeutic agents, such as alkylating agents, that also suppress bone marrow. For example, melphalan analogs are disclosed in U.S. Pat. Nos.
20 3,032,584 and 3,032,585 (see Merck Index (11th ed.) at page 914). Conventional dosages and dosage forms of melphalan are disclosed at page 1154 of Remington's Pharmaceutical Sciences, Mack Pub. Co. (18th ed. 1990).

The term "chemotherapeutic agent" also includes anti-cancer agents, such as toxins, that are targeted to cancer cells by antibodies against cancer cell
25 antigens. Such immunoconjugates are described in published PCT applications WO/97/00476 and WO/95/10940. The term chemotherapeutic agent also includes monoclonal antibody based therapies such as herceptin and rituxan (rituximab).

In conjunction with the present method chemotherapy can be given in
30 standard doses; preferably, chemotherapy is given at the upper limit of the conventional ranges or at higher than standard doses, depending on the tolerance

of the patient. Standard doses for representative chemotherapeutic agents are shown in the following Table A.

Table A

Chemotherapeutic Agent	Dose*
Doxorubicin	60-120 mg/m ² /day
Fludarabine	30-350 mg/m ² /day
Ifosfamide	5-10 g/m ² (single dose)
Thiotepa	1.5-500 mg/m ² /day
Methotrexate	12-500 mg/m ² i.v.
Mitoxantrone	10-30 mg
Estramustine	50-1120 mg/day
Bleomycin	10-30 U/m ²
Vinblastine	5-10 mg/m ²
Docetaxol	50-200 mg/m ² i.v.
Thalidomide	100-1000 mg/day
Paclitaxel	135-300 mg/m ²
Etoposide	100-5400 mg/m ² /day
Tamoxifen	20-60 mg/day
Vinorelbine	20-100 mg/m ² /day
Vincristine	1-2 mg/ m ² /day
Dexamethazone	10-60 mg/day
Busulfan	12-16 mg/kg/day
Cyclophosphamide	750-6000 mg/m ²
Carmustine	250-600 mg/m ² i.v.
Cytosine arabinoside	50-200 mg/m ² /day
Carboplatin	100-500 mg/m ² /day AUC 4-12 day

5 *Ranges from low dose given per day over multiple days to single high daily dose.

B. Adjunct Agents

The mammals (patients) can also be pre-treated with agents such as
 10 bisphosphonates, to counteract the hypercalcemia associated with certain tumors,

such as lung cancers, multiple myeloma, renal cell carcinoma, bronchogenic carcinoma, breast cancer, lymphoma, and cancers of the head and neck.

Pamidronate, clodronate, zaledronate, etidronate, tiludronate and alendronate are preferred agents for treatment of this condition. It will be appreciated that the

5 agents should be selected and used so as not to compete with the therapeutic agent for bone uptake.

The mammals (patients) can be hydrated as by oral injection, intravenous infusion, and/or by continuous bladder irrigation to reduce side effects, including kidney and bladder toxicity. For example, patients can be hydrated, with 200
10 cc/hr D5 ½ NS or similar IV fluids at least 3 hours before and until at least 6 hours after they receive the therapy dose of radionuclide complex (¹⁶⁶Ho-DOTMP or ¹⁵³Sm-EDTMP). Patients will have physical examination, ECOG performance score and pain assessment.

Patients can have bladder catheterization and irrigation (CBI) using an
15 indwelling urinary catheter starting at least one hour prior to the ¹⁶⁶Ho-DOTMP therapy dose and continuing for at least 6 hours following the therapy dose. The preferred requirements for bladder irrigation will be: i) Insert a 3-way Foley catheter one hour before the ¹⁶⁶Ho-DOTMP administration. ii) Irrigate the bladder with normal saline at the flow rate of 200 cc/hr. iii) Discontinue
20 irrigation and remove catheter after 6 hours of irrigation post the ¹⁶⁶Ho-DOTMP dose.

Patients also can be premedicated with antiemetics to decrease nausea and vomiting that may be associated with suppression of bone marrow when practicing the present invention. The preferred antiemetics are those that reduce
25 the irritation of the chemoreceptor trigger zone such as Zofran®. Common regimens that are useful in practicing the present invention include serotonin 5-HT³ antagonists such as, for example, ondansetron, granisetron, and the like; dopamine antagonists such as, for example, prochlorperazine, promethazine, droperidol, metoclopramide, and the like; antihistamines and anticholinergics
30 such as, for example, diphenylhydramine, scopolamine, dimethylhydrinate, meclizine, and the like; corticosteroids such as, for example, dexamethasone and the like; and sedatives such as, for example, diazepam, lorazepam, and the like.

C. Cancers Subject to Treatment

A wide variety of bone-associated cancers, e.g., leukemias and tumors can be treated with the present complexes. Bone-associated cancers include those cancers that have metastasized to the bone, attach to the bone, or that are associated with the skeletal system. Such cancers include bone-forming or calcific tumors, and fibro-osseous tumors, leukemias such as chronic lymphocytic leukemia and myeloid leukemia, and metastatic tumors to the skeleton. Such skeletal system tumors include, but are not limited to, sarcomas such as Ewing's sarcoma, osteochondroma, sarcoma of the periosteum, osteosarcoma, osteoma, osteoblastoma, chondrosarcoma, and giant cell tumor of the bone. Other tumors which can be treated include chordoma, adamantoma, hemangioendothelioma, hemangiopericytoma, myelomas, such as multiple myeloma, non-Hodgkin's lymphoma, Hodgkin's disease, breast cancer, prostate cancer, lung cancer, head and neck cancer, ovarian cancer, bladder cancer, liver cancer, pancreatic cancer, renal cell carcinoma, myelodysplastic syndrome, germ cell tumor, and neuroblastoma. The present method is particularly well-suited for the treatment of various forms and stages of multiple myeloma. Such forms and stages of multiple myeloma are discussed in R. Bataille et al., cited above. Myeloproliferative disorders that are not necessarily classified as cancers, including polycythemia vera, macroglobulinemia, megakaryocytic myelosis or malignant histiocytosis, can also be treated with the present complexes.

D. Adjunct Radiation Therapy

By careful aiming and regulation of dose, high-energy radiation can be used to destroy cancer cells in combination with the present radionuclide therapy. Radiation therapy (also referred to as radiotherapy, x-ray therapy, cobalt treatment, or irradiation) is presently either part of the treatment or the only treatment for about half of all cancer patients. This form of treatment is effective only for those cancer cells within the area receiving the radiation (the field), which can encompass the entirety of the subject's body (total body irradiation or TBI) or can be localized, as in the exposure of a specific tumor site.

Radiation may be used before surgery to shrink a cancerous tumor, after surgery to stop growth of any remaining cancer cells, or alone or with anticancer drugs to destroy a malignant tumor. It is particularly effective when used to treat certain types of localized cancers such as malignant tumors of the lymph nodes or vocal cords.

Radiation usually is not *per se* curative if the cancer cells have spread throughout the body or outside the area of radiation. It can be used even if a cure is not probable because it can shrink tumors, which decreases the pressure and pain they cause, or it can stop tumor bleeding.

Generally, radiation produces less physical disfigurement than radical surgery, but it may produce severe side effects. These side effects are related to the damage x-rays do to normal tissue such as blood or bone marrow. Side effects include irritated skin, swallowing difficulties, dry mouth, nausea, diarrhea, hair loss, and a loss of energy. How serious and extensive these side effects become depend on where and how much radiation is used.

Use of the present radionuclide complexes can reduce or eliminate the need for total or targeted external radiation therapy, or can enhance the total efficacy of a therapeutic regimen that normally employs TBI. Doses of TBI useful in the present method can deliver total irradiation of from about 750-1350 cGy, e.g., about 800-1000 to 1200 cGy. The total irradiation may be given in multiple fractions, i.e., 1-10 fractions; or in a single dose.

Treatment of Autoimmune Diseases and Immunosuppression

The methods and compositions of the invention are also useful to treat immunologic disorders such as autoimmune diseases by immune suppression due to temporary partial bone marrow suppression or by marrow purging, in combination with marrow transplantation. However, those skilled in the art would recognize that the methods and compositions of the invention can also be used for general immunosuppression in combination with other immunosuppressive therapies. Currently, autoimmune diseases are treated by a variety of nonspecific immunosuppressive drugs and steroids. One group of anti-inflammatory agents used in the treatment of autoimmune diseases is

corticosteroids. Corticosteroids are synthetic versions of the body's hormone cortisol, which is produced in small amounts by the adrenal gland.

Synthetically produced corticosteroids reduce inflammation and suppress the immune system. The most commonly prescribed corticosteroids for use in

5 treating autoimmune disorders are prednisone and dexamethasone.

Autoimmune disorders are sometimes treated with immunosuppressant drugs such as cytotoxic agents (e.g. methotrexate, azathioprine and

cyclophosphamide). In addition, anti-malarials including chloroquine and hydroxychloroquine can be used to suppress inflammation and the immune

10 system in the treatment of autoimmune disorders. Autoimmune diseases can

also be treated with nonsteroidal anti-inflammatory medications, such as aspirin, ibuprofen, naproxen, indomethacin, sulindac, etodolac and tolmetin. Gold salts

have been used to treat autoimmune arthritis for over a half a century, while recent advances in research have yielded new autoimmune arthritis therapies,

15 such as COX-2 inhibitors. COX-2 inhibitors (or super-aspirin) work to inhibit inflammation and pain without producing significant side effects. In addition,

another class of agents that target aberrant cytokine production, such as anti-TNF (tumor necrosis factor) drugs, can also be used for the treatment for several types

of autoimmune diseases including rheumatoid arthritis, lupus, myositis, and

20 scleroderma.

Furthermore, the methods and compositions of the invention could also be used alone or in combination with drugs that act more specifically on the immune system, for example, by blocking a particular hypersensitivity reaction.

In addition, the complexes could be used in combination with intravenous

25 immunoglobulin therapy or other antibody-based therapies, a treatment, used for various immunological diseases to reduce circulating immune complexes, or

specific T cell populations. For example, the present methods and complexes can be used as immunosuppressive agents to inhibit host rejection of

transplanted cells, tissue or organs.

30 In order to increase the chance of the patient's recovery, it can be

beneficial to employ hematopoietic cell growth factors, such as granulocyte macrophage colony stimulating factor (GM-CSF), or granulocyte colony

stimulating factor (G-CSF), and IL-11 for thrombopoiesis to stimulate or enhance the regeneration and restoration of the bone marrow. It can also be beneficial to employ stem cell growth factor, G-CSF and/or GM-CSF prior to therapy to trigger release of stem cells into the blood where they can be collected.

Infections and Infectious Diseases

The methods and compositions of the invention are also effective to treat bacterial infections, fungal infections, parasitic infections, and infectious diseases that localize to or around bone such as tuberculosis, syphilis, bacterial osteomyelitis, fungal osteomyelitis for example blastomycosis and cryptococcosis, and the like. Anti-fungal agents, and anti-bacterial agents often have poor penetration into the bone and sites enclosed by bone such as the bone marrow. In situations in which the patient is suffering from an infectious disease that has localized to the bone, the patient may be able to achieve a cure by the delivery of high doses of radiation to the bone.

Examples of agents useful in combination with targeted radiation in practicing the present invention include, but are not limited to antibiotic agents, e.g., antibacterial urinary tract agents; anti-infective agents, anti-parasitic agents and anti-fungal agents, including those disclosed in The Physician's Desk Reference, 50th Edition, 1996.

Useful antibiotic agents include systemic antibiotics, such as aminoglycosides, cephalosporins (e.g., first, second, and third generation), macrolides (e.g., erythromycins), monobactams, penicillins, quinolones, sulfonamides, and tetracyclines, including those disclosed in The Physician's Desk Reference, 50th Edition, 1996.

In addition, antibacterial agents include 2-isocephem and oxacephem derivatives disclosed in U.S. Patent No. 5,919,925; pyridonecarboxylic acid derivatives disclosed in U.S. Patent No. 5,910,498; water miscible esters of mono- and diglycerides disclosed in U.S. Patent No. 5,908,862; benzamide derivatives disclosed in U.S. Patent No. 5,891,890; 3-ammoniopropenyl cephalosporin compounds disclosed in U.S. Patent No. 5,872,249; 6-O-

substituted ketolides disclosed in U.S. Patent No. 5,866,549; benzopyran phenol derivatives disclosed in U.S. Patent No. 5,861,430; pyridine derivatives disclosed in U.S. Patent No. 5,859,032; 2-aminothiazole derivatives disclosed in U.S. Patent No. 5,856,347; penem ester derivatives disclosed in U.S. Patent No. 5,830,889; lipodepsipeptides disclosed in U.S. Patent No. 5,830,855; dibenzimidazole derivatives disclosed in U.S. Patent No. 5,824,698; alkylenediamine derivatives disclosed in U.S. Patent No. 5,814,634; organic solvent-soluble mucopolysaccharides disclosed in U.S. Patent No. 5,783,570; arylhydrazone derivatives disclosed in U.S. Patent No. 5,760,063; carbapenem compounds disclosed in U.S. Patent No. 5,756,725; N-acylpiperazine derivatives disclosed in U.S. Patent No. 5,756,505; peptides disclosed in U.S. Patent No. 5,714,467; oxathiazines and their oxides disclosed in U.S. Patent No. 5,712,275; 5-amidomethyl alpha beta-saturated and -unsaturated 3-aryl butyrolactone compounds disclosed in U.S. Patent No. 5,708,169; halogenated benzene derivatives disclosed in U.S. Patent No. 5,919,438; sulfur-containing heterocyclic compounds disclosed in U.S. Patent No. 5,888,526; and oral antibacterial agents disclosed in U.S. Patent No. 5,707,610.

Anti-parasitic agents include agents capable of killing arthropods (e.g., lice and scabies); helminths (e.g., ascaris, enterobius, hookworm, stronglyoids, trematodes, and trichuris); and protozoa (e.g., amebas, malaria, toxoplasma, and trichomonas), including those disclosed in The Physician's Desk Reference, 50th Edition, 1996.

The methods and compositions of the invention are also effective to treat fungal infections that localize to or around bone such as fungal osteomyelitis and the like. The methods and compositions can also be used in conjunction with antifungal agents known to be useful in the treatment of fungal infections. Antifungal agents include dermatological fungicides, topical fungicides, systemic fungicides, and vaginal fungicides, including those disclosed in The Physician's Desk Reference, 50th Edition, 1996.

In addition, antifungal agents include terpenes, sesquiterpenes diterpenes, and triterpenes disclosed in U.S. Patent No. 5,917,084; sulfur-containing heterocyclic compounds disclosed in U.S. Patent No. 5,888,526; carbozamides

disclosed in U.S. Patent No. 5,888,941; phyllosilicates disclosed in U.S. Patent No. 5,876,738; corynecandins derivatives disclosed in U.S. Patent No. 5,863,773; sordaridin derivatives disclosed in U.S. Patent No. 5,854,280; cyclohexapeptides disclosed in U.S. Patent No. 5,854,213; terpene compounds disclosed in U.S. Patent No. 5,849,956; agents derived from *aspergillus fumigatus* disclosed in U.S. Patent No. 5,873,726; inula extracts disclosed in U.S. Patent No. 5,837,253; lipodepsipeptides disclosed in U.S. Patent No. 5,830,855; polypeptides disclosed in U.S. Patent No. 5,824,874; pyrimidone derivatives disclosed in U.S. Patent No. 5,807,854; agents from *sporomicrobia* disclosed in U.S. Patent No. 5,801,172; cyclic peptides disclosed in U.S. Patent No. 5,786,325; polypeptides disclosed in U.S. Patent No. 5,773,696; triazoles disclosed in U.S. Patent No. 5,773,443; fusaric acids disclosed in U.S. Patent No. 5,773,421; terbenzimidazoles disclosed in U.S. Patent No. 5,770,617; and agents obtained from hormones disclosed in U.S. Patent No. 5,756,472.

15

Pathologies Treatable by BMT or Stem Cell Replacement

The present methods can be useful to ablate bone marrow in treatment regimens intended to correct a variety of disorders by replacing "defective" hematopoietic cells, with "normal" autologous or allogeneic bone marrow or stem cells. This can be used in the treatment of diseases of red cells and bleeding disorders. These include hematopoietic genetic diseases such as hemolytic anemias, i.e., sickle cell anemia or thalassemia. Other such disorders include various anemias, polycythemia, thrombocytopenia, and bleeding disorders related to defective platelet function or abnormalities in clotting factors.

25

Hematopoietic stem cell transplantation from normal donor has been reported to be effective to treat lysosomal and peroxisomal storage diseases, such as globoid cell leukodystrophy, metachromatic leukodystrophy, adrenoleukodystrophy, mannosidosis, flucosidosis, aspartylglucosaminuria; Harder, Maroteaux-Lamy and Sly Syndromes and Gaucher disease type III. W. Krivit et al., Curr. Opin. Neurol., 12, 167 (1999).

30

Gene Therapy

The present method can also be employed as part of gene therapy that involves implantation of genetically engineered stem cells, to correct genetic defects, following bone marrow ablation. For example, a subject's own stem
5 cells can be "normalized" by introduction of a vector comprising a gene that will effectively counteract the defective gene or replace the missing one. See, D.B. Kohn, Curr. Opinion in Pediatr., 7, 56 (1995).

Bone marrow suppression, followed by administration of genetically engineered (transformed) stem cells, can be used, for example, in the treatment
10 of cancer in a human by inserting exogenous genes into human primary cells, such as, for example, stem cells, which specifically "target" mature blood cells to a tumor. Preferably, the stem cells have been removed from a cancer patient and expanded in culture. Genes that enhance the anti-tumor effects of the mature cells can also be employed. The blood cells can be expanded in number before
15 or after insertion of the genes. A method for transforming blood cells is described in U.S. Pat. No. 5,286,497. Thus, the procedure is performed in such a manner that upon injection into the patient, the transformed blood cells will produce an anti-cancer agent in the patient's body, preferably at the site of the tumor itself.

20 The gene carried by the transformed stem cells can be any gene that directly or indirectly enhances the therapeutic effects of the resultant mature blood cells such as a recombinant normal human gene. The gene carried by the stem cells can be any gene that allows the blood cells to exert a therapeutic effect that it would not ordinarily have, such as a gene encoding a clotting factor useful
25 in the treatment of hemophilia. Examples of other suitable genes include those that encode cytokines such as TNF, interleukins (interleukins 1-12), interferons (α , β , γ -interferons), T-cell receptor proteins and Fc receptors for antigen-binding domains of antibodies, such as immunoglobulins.

Additional examples of suitable genes include genes that modify blood
30 cells to "target" to a site in the body to which the blood cells would not ordinarily "target," thereby making possible the use of the blood cell's therapeutic properties at that site. In this fashion, blood cells can be modified, for example,

by introducing a Fab portion of a monoclonal antibody into the stem cells, thereby enabling the mature blood cells to recognize a chosen antigen. Other genes useful in cancer therapy can be used to encode chemotactic factors that cause an inflammatory response at a specific site, thereby having a therapeutic effect. Other examples of suitable genes include genes encoding soluble CD4 which is used in the treatment of AIDS and genes encoding preselected polypeptides or protein that can act to correct or ameliorate genetic disorders which result in insufficient or defective enzymes. Such genes include the α -antitrypsin gene, which is useful in the treatment of emphysema caused by α -antitrypsin deficiency, a tyrosine hydroxylase gene (Parkinson's disease), a glucocerebrosidase gene (Gaucher's disease), an α -galactosidase gene (Fabry's disease) an arylsulfatase A gene (metachromatic leukodystrophies), an insulin gene for use in diabetes, or genes encoding other polypeptides or proteins.

The gene therapy of the present invention is also useful in the treatment of a variety of diseases including but not limited to adenosine deaminase deficiency, sickle cell anemia, thalassemia, hemophilia, diabetes, α -antitrypsin deficiency, brain disorders such as Alzheimer's disease, and other illnesses such as growth disorders and heart diseases, for example, those caused by alterations in the way cholesterol is metabolized and defects of the immune system.

One of skill in the art would recognize that the conditions discussed herein above can have multiple causes and can overlap in naming and categorization.

The following examples are included to aid in the understanding of the invention but are not to be construed as limiting the invention.

EXAMPLE 1

^{166}Ho -DOTMP Preparation

Ho-165-nitrate targets are prepared from dissolution of holmium oxide in nitric acid followed by reduction to dryness. A target containing 6 mg of holmium is irradiated in a reactor for approximately 155 hours at a flux of 4.5×10^{14} n/cm²/s. The specific activity is typically in the range of 1.3 - 2 Ci/mg.

The ^{166}Ho -nitrate target is dissolved in 0.3 N HCl. In a typical 9 Ci preparation, ^{166}Ho -chloride is supplied in 10 ml of 0.3 N HCl. Six vials of DOTMP (each vial containing 10 mg DOTMP and 28 mg NaOH) is dissolved in 4 ml water and added to the ^{166}Ho chloride. The ligand to metal ratio is 3.5. The reaction mixture is allowed to mix for 10 minutes at a pH of 10.5. This is followed by addition of 4.8 ml of 1.0 M sodium phosphate buffer and ascorbic acid. The final concentration of ascorbic acid is 55 mg/ml. Dilution with water may be performed to assure that the final activity concentration does not exceed 322 mCi/ml. The pH of the final product is 7 - 8.

10

EXAMPLE 2

Preparation of ^{153}Sm solution

Sm-153 is produced by irradiating 99.06 percent enriched $^{152}\text{Sm}_2\text{O}_3$ in the first row reflector at a neutron flux of 8×10^{13} neutron/cm² x sec, or at high flux of 4.5×10^{14} n/cm²/sec, at the Missouri University Research Reactor (MURR). Irradiations are generally carried out for 50 to 60 hours, yielding a Sm-153 specific activity of 1000-1300 Ci/g.

To irradiate Sm_2O_3 for production of Sm-153, the desired amount of target is first weighed into a quartz vial, the vial flame sealed under vacuum and welded into an aluminum can. The can is irradiated for the desired length of time, cooled for several hours and opened remotely in a hot cell. The quartz vial is removed and transferred to a glove box, opened into a glass vial that is then sealed. An appropriate amount of a solution of hydrochloric acid is then added to the vial via syringe in order to dissolve the Sm_2O_3 . Once the Sm_2O_3 is dissolved, the samarium solution is diluted to the appropriate volume by addition of water. The solution is removed from the original dissolution vial that contains the shards of the quartz irradiation vial, and transferred via syringe to a clean glass serum vial.

EXAMPLE 3

Preparation of ^{159}Gd solution

Gadolinium-159 is prepared by sealing gadolinium oxide (1.1 mg) into a quartz vial. The vial is welded inside an aluminum can and irradiated for 30
5 hours in a reactor at a neutron flux of 8×10^{13} neutron/cm² x sec. The contents of the quartz vial are dissolved using HCl. Water is added to obtain a solution of Gd-159 in 0.1N HCl.

EXAMPLE 4

10 Preparation of ^{153}Sm -EDTMP

The EDTMP ligand (25 mg) is dissolved in 0.75 mL of distilled water in a vial. To this, 2.5 mL of ^{153}Sm solution in 0.1N HCl is added. The pH is adjusted to 10 using NaOH and the solution is heated to 60-70°C for 30 min. in a water bath. The pH is then adjusted to 7-8 with HCl.

15

EXAMPLE 5

Preparation of ^{166}Ho -DOTMP

The DOTMP ligand (22 mg) was dissolved in 878 μL of distilled water and 15 μL of 50% NaOH. A volume of 30 μL of this solution was transferred to
20 a vial containing 1.5 ml of Ho solution (0.6 mM Ho in 0.1N HCl spiked with 2 μL of ^{166}Ho tracer). The pH was adjusted to 7-8 using NaOH and the amount of Ho found as a complex was greater than 99% as determined by ion exchange chromatography. This yielded a solution containing 0.6 mM Ho with a ligand to metal molar ratio of approximately 1.5.

25

EXAMPLE 6

Pharmacokinetics and Patient Specific Dosimetry of High Dose ^{166}Ho -DOTMP Therapy used for Treatment of Breast Cancer Metastatic to Bone

Eight patients with breast cancer metastatic only to bone initially received
30 a 30 mCi dose of ^{166}Ho -DOTMP for diagnostic purposes. Pharmacokinetics were assessed via whole body counting, gamma camera imaging, and urine and

blood assays for the first 48 hours following injection. Patients were followed with autologous stem cell transplantation for rescue from hematologic toxicity.

The average percentage uptake in the skeleton was $28 \pm 12\%$ (range: 15% to 47%), with an effective skeletal half-life of 19.9 ± 2.5 hours (range: 15 to 23 hours). Approximately 50% of the material was present in the urine at 6 hours post injection. Whole blood clearance was rapid and biphasic: early $T_{1/2}$: 0.05 ± 0.04 hours; late $T_{1/2}$: 11 ± 4 hours with, on average, a small percentage of the injected dose remaining at 24 hours post injection.

Therapy doses were calculated based upon prescribed dose to the red bone marrow using the Medical Internal Radiation Dose (MIRD) technique and percentage localization in the skeleton. Appropriate S-values were provided by Oak Ridge National Laboratory. The desired target dose was 22 Gy to the red marrow calculated by the above technique for each individual. The average red marrow dose was calculated to be 1.97 ± 0.92 cGy/mCi (range: 0.98 cGy/mCi to 3.19 cGy/mCi). Three patients proceeded to therapy, two were disqualified due to low uptake in the skeleton ($<30\%$; revised qualification: 15%), and three were disqualified for other reasons unrelated to the ^{166}Ho -DOTMP treatment. Other than severe hematological suppression, no toxicity was noted.

EXAMPLE 7

^{166}Ho -DOTMP-Melphalan Treatment of Multiple Myeloma (MM) Patients

Multiple myeloma patients (≤ 65 yrs. of age) that have responded to initial chemotherapy or have primary refractory disease or chemotherapy responsive relapse, but who are not in refractory relapse are treated. Patients are well hydrated with fluids during the day prior to the diagnostic dose. An initial diagnostic dose of 30 mCi of ^{166}Ho -DOTMP is administered to confirm the selective localization to the skeleton, establish the in-vivo pharmacokinetics and provide radiation dosimetry estimates for the red marrow. Assuming $>15\%$ of the ^{166}Ho -DOTMP accumulates in bone following the injection, the amount of ^{166}Ho -DOTMP required for therapy is calculated based on delivering a specified radiation absorbed dose to the marrow. Patients receive the therapeutic dose by

intravenous injection over 5-10 minutes, given over 1-3 days \geq 48 hrs after the dosimetry (test) dose.

The time line for conducting the investigation is as follows: Test dose ^{166}Ho -DOTMP (30 mCi); ^{166}Ho scan image (0, 4-6, 20-24 hr.); Blood samples
5 for dosimetry (10, 30 min, 1, 2, 6, 20-24 hr.); Urine samples (0-6, 6-12, 12-24, 24-48 hr.); and External whole body probe (0, 2, 6, 24 and 48 hr.).

Melphalan is administered 48 hr prior to the predicted PBSC infusion based upon dosimetry assessment from the test dose. PBSC infusion is administered when bone marrow dose from ^{166}Ho is ≤ 1 cGy/hr. Patients were
10 treated at 20, 30, 40 and prospectively 50 Gy, and with 140 mg/m² and 200 mg/m² melphalan. The results are shown in Table 2, hereinbelow.

The MTD was defined as the level that is associated with a true toxicity rate of 20%, where toxicity for these purposes was taken to be grade 3 or greater extramedullary drug related toxicity.

15 All toxicities encountered during the study will be evaluated according to Bearman criteria (Bearman *et al.*, J Clin Oncol, 6,1562, (1988)). Graft failure is considered a grade 3 toxicity. Graft failure is defined as failure to recover granulocytes to $0.5 \times 10^9/\text{l}$ or platelets $20 \times 10^9/\text{l}$ within 28 days of transplant or a
20 fall to less than these levels for 3 or more consecutive days after day 28 without other apparent cause. Hematopoietic recovery (engraftment) is defined as having a sustained granulocyte count of $0.5 \times 10^9/\text{l}$ for two consecutive counts post transplant and a platelet count $20 \times 10^9/\text{l}$ for seven consecutive counts post
25 transplant, without transfusion support. The first of two counts for the granulocyte count and the first of seven counts for the platelet count are considered the day of engraftment.

Patients undergo blood stem cell infusion at the time when ongoing radiation to the marrow falls to < 1 rad/hr, and at least 24 hours after melphalan infusion. The total volume of stored cells is infused into a free flowing IV line primed with normal saline. Patients are premedicated with acetaminophen 650
30 mg PO and diphenhydramine 50 mg PO or IV. All patients receive conventional supportive care for autologous/syngeneic blood and marrow transplantation, (such as allopurinol, menstrual suppression, prophylactic antibiotics, empiric

antibiotics, IV Ig, transfusions of blood products, hyperalimentation, and the like).

EXAMPLE 8

Single Dose ^{166}Ho -DOTMP Treatment with Melphalan

5 Well hydrated mammals (humans should be instructed to take in fluids in excess of 2000 cc during the prior 24 hours) are administered an initial diagnostic dose of 30 mCi to confirm the selective localization to the skeleton, establish the in-vivo pharmacokinetics, skeletal uptake, and provide radiation dosimetry estimates for the red marrow. The actual dosage is of the ^{166}Ho
10 required for therapy will be calculated on the basis of percent uptake in the skeleton and that value used to deliver the specified radiation absorbed dose to the marrow. Patients will receive the therapeutic dose of 20 Gy (370-1110 megabecquerels per kilogram of body weight) or 30 Gy (555-1665 megabecquerels per kilogram of body weight) or 40 Gy (740-2220
15 megabecquerels per kilogram of body weight) or 50 Gy (925-2775 megabecquerels per kilogram of body weight) by intravenous injection over 2-10 minutes given on a single day. The mammals are then administered melphalan, 140 mg/m², 200 mg/m² or 220 mg/m², 48 hours prior to stem cell (PBSC) infusion which occurs about 6-8 days after ^{166}Ho -DOTMP administration, when
20 the bone marrow exposure rate drops below 1 cGy/hour. Mammals are started on granulocyte-colony stimulating factor (G-CSF) at a dose of 5-10 mcg/kg/day, and continued until the granulocyte count is $1 \times 10^9/\text{L}$ for 3 consecutive days. Mammals are also administered prophylactic antibiotic and antifungal agents while neutropenic.

25

EXAMPLE 9

Dosimetry Study

A 12-patient, Phase II multicenter study was performed to further evaluate the safety, biodistribution and pharmacokinetics of ^{166}Ho -DOTMP.
30 Each patient was to receive two 30 mCi tracer doses of ^{166}Ho -DOTMP followed, in eligible patients (those with adequate skeletal uptake parameters), by a therapy

dose calculated to deliver 25 Gy to the red marrow. All patients in this study received CBI.

Serum and urine pharmacokinetics were reproducible within patients, and were consistent with renal excretion as the primary route of excretion of ¹⁶⁶Ho-DOTMP. Gamma camera counting and urine PK confirmed that there was no route of excretion other than the urine. Gamma camera counting was used reliably to assess whole body clearance of ¹⁶⁶Ho-DOTMP. Gamma camera images showed that retained activity was localized in the skeleton. No clinically significant differences were observed between the skeletal uptake and pharmacokinetics of tracer doses administered as a bolus push, compared to a 15-minute infusion.

All patients were eligible to receive the therapy dose of ¹⁶⁶Ho-DOTMP. The dose administered ranged from 1014 to 1776 mCi (551 to 860 mCi/m²). All patients engrafted within 15 days of stem cell transplant, and no unexpected acute toxicities were noted. Close monitoring of serum calcium levels, as well as ECG and Holter tracings were carried out, and no clinical observations of hypocalcemia or associated cardiac abnormalities were noted. Follow-up evaluations are ongoing to determine efficacy and the incidence of late toxicity in these patients.

20

EXAMPLE 10

¹⁶⁶Ho-DOTMP Treatment

Well hydrated mammals (Humans should be instructed to take in fluids in excess of 2000 cc during the prior 24 hours.) are administered an initial diagnostic dose of 30 mCi to confirm the selective localization to the skeleton, establish the in-vivo pharmacokinetics, skeletal uptake, and provide radiation dosimetry estimates for the red marrow. The actual dosage of the ¹⁶⁶Ho required for therapy will be calculated on the basis of percent uptake in the skeleton and that value used to deliver the specified radiation absorbed dose to the marrow. Patients will receive the therapeutic dose of 50 Gy (2000-3000 megabecquerels per kilogram of body weight) by intravenous injection over 2-10 minutes given on a single day. When the bone marrow exposure rate drops below 1 cGy/hour

mammals are started on granulocyte-colony stimulating factor (G-CSF) at a dose of 5-10 mcg/kg/day, and continued until the granulocyte count is $1 \times 10^9/\text{L}$ for 3 consecutive days. Mammals are also administered prophylactic antibiotic and antifungal agents while neutropenic.

5

EXAMPLE 11

Patients, afflicted with multiple myeloma, were treated according to the method of the present invention. The dosage range of radiation from the complex was 460 mCi to 4.5 Ci.

10 Fifty-three patients received intravenous hydration only, while 30 patients received both IV hydration and continuous bladder irrigation. The results for 40 patients are described in Table 2, below. These results demonstrate that the combination of 200 mg/m^2 melphalan and Ho-DOTMP is at least as efficacious or is more efficacious than the combination of 140 mg/m^2 melphalan with Ho-

15 DOTMP, either with or preferably without TBI.

Table 2

	140 mg/m ² melphalan w/o TBI			140 mg/m ² melphalan w/ TBI			200 mg/m ² melphalan w/o TBI		
Ho-DOTMP Dose to Marrow:	20 Gy	30 Gy	40 Gy	20 Gy	30 Gy	40 Gy	20 Gy	30 Gy	40 Gy
Days to ANC > 500	10 (8-13)	16 (13-17)	12 (9-13)	9 (9-16)	11 (9-14)	9 (9-10)	10 (10-10)	12 (9-19)	10.5 (9-13)

Complete Response	3/14			7/17			8/9		

ANC = Absolute neutrophil count
NA = Not Available

Protocols enrolling patients using ^{166}Ho for multiple myeloma have accrued 88 patients, with 77 evaluable for response. The original protocol treating patients with melphalan (140 mg/m^2) without TBI was amended to increase the dose of melphalan to 200 mg/m^2 . The increase in melphalan was to determine if ^{166}Ho -DOTMP could be given in combination with high dose melphalan without added unmanageable toxicity.

In order to achieve a complete response using protocol criteria, a patient must have a complete absence of any myeloma protein in the blood/urine and marrow post treatment. The patient must have normal bone marrow with complete resolution of plasmacytomas and no increase in bone lesions. To meet international standards, this must be maintained for 6 weeks. While response rates to a conventional high dose therapy vary widely, in general for previously treated patients, there is a range of 5-25% CR rate.

Partial response is defined as sustained decrease in the production rate of the monoclonal serum protein to 25% or less of the pretreatment value for at least 2 months. Calculations consider the serum myeloma protein concentration, variations in catabolic rate with changing concentration, and changes in estimated plasma volume. Response requires a sustained 24 hour urine Bence Jones protein excretion to less than 0.1 gm/day for at least 2 measurements.

Based on the 77 patients that have response data and have been monitored, currently there is a 35% complete response rate across all ^{166}Ho -DOTMP/melphalan \pm TBI doses (29 patients). Twenty-four patients had a partial response. Of the 40 patients who received 200 mg/m^2 melphalan and were not in CR at the time of treatment, 16 (39%) achieved complete remission, and 13 (32%) achieved partial response. Sixty-one percent of these patients were alive at a mean follow-up time of 39.4 months. (The nine patients who received a dose of 750 mCi/m^2 ($\pm 10\%$) achieved a CR rate of 44.4% and a 2-year survival of 100%).

To date, the bladder pathology Grade 1-3 hemorrhagic cystitis (HC) has been observed in 24 patients, 22 of whom were treated without continuous bladder irrigation (CBI). Of the two patients who received CBI and experienced this toxicity, one had microscopic hematuria and received prior external radiation

to the bladder. The other case was complicated by BK virus and other prior infections plus previous Cytoxan® treatment, which are known causes of hemorrhagic cystitis. These data demonstrate that CBI aids in minimizing the incidence and severity of hemorrhagic cystitis following administration of ¹⁶⁶Ho-DOTMP.

Symptoms of long-term kidney dysfunction occurred in 33 (40%) of the 83 patients 5-12 months post-therapy. Twenty-five percent of the patients developed grade 3-4 renal toxicity. Seven patients have developed the renal dysfunction, thrombotic thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS), that is possibly related to the test agent. Three patients had received total body irradiation. Five of the seven patients also had severe viral illnesses, which are known predisposing factors to TTP/HUS, as is hematopoietic transplant. Five of the seven patients also had HC and five of the seven did not receive CBI. All seven patients were treated at the same dose level of 40 Gy or higher to the marrow. Five of these patients received melphalan at a dose of 200 mg/m². Two patients received a marrow dose of approximately 48 Gy but in conjunction with 140 mg/m² melphalan and 800 cGy of total body irradiation, fractionated over four days. To date, four of the seven patients have died.

The etiology of renal dysfunction in patients with multiple myeloma is often complex. To date, nine patients have experienced renal dysfunction that was not related to TTP/HUS or progressive myeloma. These patients had serum creatinine > 2 mg/dL on two occasions or > 3 mg/dL on one occasion. Four patients received 8 Gy of TBI in addition to ¹⁶⁶Ho-DOTMP and several patients had ureteral outlet obstruction secondary to hemorrhagic cystitis.

To date, there have been 21 patient deaths in the Phase I/II studies, four of which were the result of TTP/HUS and were considered possibly related to the agent, although two had progressive multiple myeloma. The remaining deaths were considered unrelated to the study drug: eleven were due to disease progression, one was due to complications associated with sepsis, one was due to lung cancer, two were due to complications associated with RSV and infection, and two were related to PCP pneumonia.

Although this incidence of renal side effects was unexpected, it is believed that lowering the administered dose of ^{166}Ho -DOTMP to about 725-775 mCi/m² while maintaining thorough hydration of the patients during dosing will lower the incidence of sustained renal dysfunction to an acceptable level, e.g., to no more than about 25% of the treated population preferably to less than 10-15%. Such dosing will deliver a mean dose of radiation to the marrow of about 20-30 Gy, which is at the lower end of the Table 2 ranges.

Of the 37 patients in the study who received ≤ 30 Gy marrow dose from ^{166}Ho -DOTMP, 35 were evaluable. Of these, 30% had a complete response, 32% had a partial response and 32% had stable disease. None had progressive disease and the survival of 12 months was 100%.

EXAMPLE 12

Treatment: 40 Gy ^{166}Ho -DOTMP, Melphalan 140 mg/m²

The patient, a 47 year-old male with an original diagnosis of multiple myeloma, was administered a therapeutic dose of ^{166}Ho -DOTMP of 3875 mCi which was calculated to deliver 40 Gy to the marrow. Post ^{166}Ho -DOTMP, the patient received a dose of 140 mg/m² of melphalan (I.V.). The patients stem cells were reinfused three days after the melphalan and were followed by G-CSF for ten days.

Nine days post stem cell transplant, the patient engrafted neutrophils (ANC >500), and fourteen days post transplant, the patient engrafted platelets (>20,000). Twenty-eight days post transplant the patient was in complete remission.

EXAMPLE 13

Treatment with 750 mCi/m² ^{166}Ho -DOTMP + 200 mg/m² Melphalan

Based on the results of the studies of Example 11, a multicenter Phase III study will be carried out to evaluate the efficacy of a 750 mCi/m² dose of ^{166}Ho -DOTMP in patients with primary refractory multiple myeloma. Eligible patients will be registered and enrolled on study. The study design includes administration of a tracer dose to estimate bone uptake and determine eligibility

to receive the therapy dose. Patients considered to have an acceptable bone uptake will then receive the high dose therapy regimen. Patients who do not meet the entry criteria based on bone uptake will be withdrawn from study and will be followed for safety for 28 days.

5 The therapy dose of ^{166}Ho -DOTMP will be followed by melphalan 200 mg/m^2 and peripheral blood stem cell transplant (PBSCT). The primary endpoints include evaluation of the efficacy and safety of 750 mCi/m^2 ^{166}Ho -DOTMP in this patient population. Efficacy will be assessed as the complete response (CR) rate at 6 months post-transplant. Safety evaluations will include
10 engraftment and incidence of clinical adverse events. In addition, evaluation of the long-term efficacy of this dosing methodology, including survival and event-free survival, will be carried out.

 A 30 mCi tracer dose of ^{166}Ho -DOTMP will be administered to determine patient eligibility. Patients will be eligible for the therapy dose only if
15 the tracer dose shows no aberrant uptake and skeletal residence time of at least 5.76 hours. (This is based on the uptake cut-off from previous trials, $\text{FxT}_e \geq 4$, converting it to residence time by multiplying by 1.44 to derive residence time.) This ensures that only patients with adequate skeletal uptake are treated with ^{166}Ho -DOTMP.

20 A patient deemed eligible for ^{166}Ho -DOTMP therapy based on the tracer dose will then be hydrated ($250\text{-}500 \text{ cc/hr}$ NS i.v. and continuous bladder irrigation (200ml/hr). ^{166}Ho -DOTMP will be administered i.v. over $5\text{-}15$ minutes at a dose of 750 mCi/m^2 (based on patient's BSA on the day of tracer dose administration; a maximum of 1500 mCi total will be allowed). Melphalan
25 at 200 mg/m^2 will be administered 5 to 9 days later, followed by AHSCS 24 to 48 hours after melphalan (minimum of $2 \times 10^6/\text{kg}$ of $\text{CD}34^+$ cells). The transplant day (day of stem cell infusion) will be defined as Day 0.

 The patient will be followed for safety assessments for 10 years. Efficacy assessments will occur at Months 3 , 6 , 9 , and 12 , and disease relapse or
30 progression will be documented until Year 3 .

 An interim analysis of the organ dosimetry for the first 20 patients will be performed to confirm that dose to the kidney is not significantly higher than that

seen in prior trials. Additionally, another interim analysis will be performed after 6 months of follow-up has been completed on the first 20 patients, to rule out lack of efficacy of ^{166}Ho -DOTMP.

The selection of 750 mCi/m^2 as the fixed dosage is based on retrospective data analysis from Example 11. At this dose level, the response rate was similar to higher dose levels and the toxicity was acceptable. The incidence of TTP/HUS and of Grade 3-4 renal toxicity, survival rate, and CR rate as a function of dosage was analyzed in this patients. Nine patients received a dosage of $750 \pm 10\% \text{ mCi/m}^2$ ($675 - 825 \text{ mCi/m}^2$). Of these, there were no cases of TTP/HUS, no cases of Grade 3-4 renal toxicities, 4 complete responses (44.4%), and a 2-year landmark survival of 100%. In addition, no cases of TTP/HUS occurred in patients treated at doses, 675 mCi/m^2 . The results of this analysis confirm that a dosage of 750 mCi/m^2 was not associated with cases of TTP/HUS or Grade 3-4 renal toxicity, whereas the CR and survival rates are highest at this dosage level.

Further, a cap of 1500 mCi for patient with $\text{BSA} > 2 \text{ m}^2$ will help ensure patient safety. Twenty-two patients in the earlier trials received 1500 mCi or less and 61 patients received more than 1500 mCi. There have been no reported cases of TTP and Grade 3 or high renal toxicity among patients who were administered less than 1500 mCi of ^{166}Ho . The incidence of sustained renal dysfunction in patients who received less than 1500 mCi is 23% and is almost 50% less than the incidence in patients who received more than 1500 mCi. Two-year survival is slightly higher in patients who received $\leq 1500 \text{ mCi}$, 77% vs. 67%, and CR rate is comparable, 32% vs. 36%. Based on the experience of patients administered $\leq 1500 \text{ mCi}$, serious toxicities will likely be prevented and overall renal toxicities will occur at incidence rates similar to those typically seen in multiple myeloma patients. In addition, efficacy will be maintained at levels comparable to those observed at higher dosages.

Melphalan 200 mg/m^2 is the most commonly used preparative regimen for patients with multiple myeloma, due to its efficacy and safety profile, and it will be administered in this study at 200 mg/m^2 . Melphalan will provide additional antitumor activity in the bone marrow and to non-skeletal sites of

disease. In the earlier studies, melphalan at 200 mg/m² plus ¹⁶⁶Ho-DOTMP was well tolerated.

EXAMPLE 14

5 Treatment: 40 Gy ¹⁵³Sm-EDTMP, Melphalan 200 mg/m²

 The patient, a 58 year-old female with an original diagnosis of multiple myeloma and diagnosed with primary refractory disease, is given a trace dose of ¹⁵³Sm-EDTMP, and the 24 hr whole body uptake is calculated. Based on dosimetry calculations a therapeutic dose is designed to deliver 40 Gy to the
10 marrow. After the level of ¹⁵³Sm in the patient fell to ≤3.6 mCi, the patient receives a dose of 200 mg/m² of melphalan (I.V.). The patient's stem cells are reinfused two days after the melphalan, with G-CSF and antibiotics, as needed.

 Fourteen days post stem cell transplant the patient engraftsd neutrophils (absolute neutrophil count (ANC) > 500), and twenty days post transplant the
15 patient engrafts platelets (> 20,000). Five months post treatment the patient is determined to have a complete remission.

EXAMPLE 15

Stability of Metal Ligand Complexes With Stabilizer

20 Samples of ¹⁶⁶Ho-DOTMP were prepared according to the procedure in Example 1 using ascorbic acid, 55 mg/mL, as the stabilizer. Identical samples were prepared without ascorbic acid. The solutions were analyzed for radiochemical purity after 1 hour, 6 hours, 10 hours, 24 hours, and 48 hours, using Instant Thin Layer Chromatography (ILTC), Cation Exchange
25 Chromatography (CEC) and High Performance Liquid Chromatography (HPLC). As can be seen in the Table 3, the use of a radioprotectant (stabilizer) allowed the sample to maintain high radiochemical purity over samples without any stabilizer.

Table 3

Time (hrs)	1	6	10	24	48
ITLC					
Without stabilizer	99.2	98.1	97.5	97.6	96.5
With stabilizer	99.0	99.2	99.6	99.6	99.6
CEC					
Without stabilizer	99.0	97.8	97.8	97.2	97.1
With stabilizer	98.4	99.0	99.6	98.5	98.7
HPLC					
Without stabilizer	100	95.4	94.9	85.8	
With stabilizer	100	100	99.0	98.7	

EXAMPLE 16

5 Biodistribution Study of ^{166}Ho -DOTMP in Rats

Sprague Dawley (S. D.) rats were injected intravenously (inj. i.v.) with a solution of ^{166}Ho -DOTMP ("Ho-DO") containing ascorbic acid (asc) as a stabilizer. The animals were sacrificed and organs excised and counted in a radioactive well counter after decay to appropriate levels. Bone (femur) samples were counted and converted to a total bone percent injected dose using a factor of 25 times femur percent.

A second group of Sprague Dawley rats were injected intravenously with a solution of ^{166}Ho -DOTMP without having the stabilizer. The animals were sacrificed and organs excised and counted in a radioactive well counter after decay to appropriate levels. Bone (femur) samples were counted and converted to a total bone percent injected dose using a factor of 25 times femur percent.

The results of this study show that the addition of the stabilizing agent, ascorbic acid, lowered the uptake of radiation by the non-target organs, while equivalent bone uptake was seen. In both control and stabilized preparations, high uptake and specificity for skeletal targeting was shown.

Results are illustrated summarized in Tables 4-6 and in Figures 2-4. Figure 2 illustrates the data uptake base on the % injection dose. Figure 3 illustrates the data uptake base on the % injection dose per gram(mass). Figure 4

illustrates the data uptake base on the tissue/blood ratio. Abbreviations: Blo = blood; Tai = tail; Lun = lung; Liv = liver; Spl = spleen; Sto = stomach; Kid = kidneys; Int = intestines; Bon = bone; SD = standard deviation.

EXAMPLE 17

5 Treatment of breast cancer will be in conjunction with high-dose
combination chemotherapy regimens such as CTCb (STAMP V):
Cyclophosphamide 1500 mg/m², Thiotepa 125 mg/m², Carboplatin 200 mg/m²
administered intravenously over one or several days. Chemotherapeutics will
preferably be administered following the Ho-DOTMP but may be given prior to
10 or simultaneously.

EXAMPLE 18

Breast cancer, particularly metastatic breast cancer, will be treated with
the present complexes, e.g., with ¹⁶⁶Ho-DOTMP in accord with the present
15 method, employing the regimens listed on Table 7.

Table 7 - Breast Cancer Regimens

Combination Regimens

Regimens	Chemotherapeutic Agent(s)
AC	Doxorubicin 40-45 mg/m ² i.v., day 1 WITH Cyclophosphamide 200 mg/m ² PO, days 3-6 Repeat cycle every 21 days OR Cyclophosphamide 500 mg/m ² i.v., day 1 Repeat cycle every 28 days
CAF(FAC)	Cyclophosphamide 600 mg/m ² i.v., day 1 Doxorubicin 60 mg/m ² i.v., day 1 Fluorouracil 600 mg/m ² i.v., days 1, 8 Repeat cycle every 28 days OR Cyclophosphamide 500 mg/m ² i.v., day 1 Doxorubicin 50 mg/m ² i.v., day 1 Fluorouracil 500 mg/m ² i.v., days 1 Repeat cycle every 21 days and day 8 (FAC)
CFM (CNF,FNC)	Cyclophosphamide 600 mg/m ² i.v., day 1 Fluorouracil 600 mg/m ² i.v., day 1 Mitoxentrone 12 mg/m ² i.v., day 1 Repeat cycle every 21 days
CMF	Cyclophosphamide 100 mg/m ² PO, days 1-14 or 600 mg/m ² i.v., days 1, 8 Methotrexate 40 mg/m ² i.v., days 1, 8 Fluorouracil 600 mg/m ² i.v., days 1,8 Repeat cycle every 28 days OR Cyclophosphamide 600 mg/m ² i.v., day 1 Methotrexate 40 mg/m ² i.v., day 1 Fluorouracil 600 mg/m ² i.v., day 1 Repeat cycle every 21 days
NFL	Mitoxantrone 12 mg/m ² i.v., day 1 Fluorouracil 350 mg/m ² i.v., days 1-3, after Leucovorin Leucovorin 300 mg i.v., over 1 hour, days 1-3 OR Mitoxantrone 10 mg/m ² i.v., day 1 Fluorouracil 1,000 mg/m ² /d CI, days 1-3, after leucovorin Leucovorin 100 mg/m ² i.v., over 15 minutes, days 1-3 Repeat cycle every 21 days

Regimens	Chemotherapeutic Agent(s)
Sequential Dox-CFM	Doxorubicin 75 mg/m ² i.v., every 21 days, for 4 cycles followed by 21- or 280 day CMF for 8 cycles
VATH	Vinblastine 4.5 mg/m ² i.v., day 1 Doxorubicin 4.5 mg/m ² i.v., day 1 Thlotepa 12 mg/m ² i.v., day 1 Fluoxymesterone 20 or 30 mg/d PO Repeat cycle every 21 days
Vinorelbine Doxorubicin	Vinorelbine 25 mg/m ² i.v., days 1, 8 Doxorubicin 50 mg/m ² i.v., day 1 Repeat cycle every 21 days

Single-Agent Regimens

Regimens	Chemotherapeutic Agent(s)
Anastrozole	Anastrozole 1 mg/d PO
Capecitabine	Capecitabine 1,250 mg/m ² PO bid, days 1-14 Repeat cycle every 21 days
CFM (CNF,FNC)	Cyclophosphamide 600 mg/m ² i.v., day 1 Fluorouracil 600 mg/m ² i.v., day 1 Mitoxentrone 12 mg/m ² i.v., day 1 Repeat cycle every 21 days
Docetaxel	Docetaxel 60-100 mg/m ² i.v, over 1 hour, every 21 days
Gemcitabine	Gemcitabine 725 mg/m ² i.v, over 30 minutes weekly for 3 weeks, followed by 1 week rest Repeat cycle every 28 days
Letrozole	Letrozole 2.5 mg/d PO
Megestrol	Megestrol 40 mg PO bid
Pacitaxel	Pacitaxel 250 mg/ m ² i.v, over 3 or 24 hours every 21 days OR Pacitaxel 175 mg/m ² i.v., over 3 hours, every 21 days
Tamoxifen	Tamoxifen 10 or 20 mg twice daily or 20 mg/d PO
Toremifene citrate	Toremifene citrate 60 mg/d PO
Vinorelbine	Vinorelbine 30 mg/m ² i.v, every 7 days

EXAMPLE 19

Prostate cancer, particularly metastatic prostate cancer will be treated with the present complexes, e.g., with ^{166}Ho -DOTMP, in accord with the present method, employing the regimens listed on Table 8.

5

Table 8 - Prostate Cancer Regimens
Combination Regimens

Regimen	Chemotherapeutic Agent(s)
Estramustine Vinblastine	Estramustine 200 mg/m ² PO, tid, days 1-42 Vinblastine 4 mg/m ² i.v., weekly for 6 weeks, begin day 1 Repeat cycle every 8 weeks
FL	Flutamide 250 mg PO, tid WITH Leuprolide acetate 1 mg/d SQ OR Leuprolide acetate depot 7.5 mg IM, every 28 days i.v., day 1
FZ	Flutamide 250 mg PO, tid WITH Goserelin acetate 3.6 mg implant SQ, every 28 days OR Goserelin acetate 10.8 mg implant SQ every 12 weeks Begin regimen 2 months prior to radiotherapy
Mitoxantrone Prednisone	Mitoxantrone 12 mg/m ² i.v., day 1 Prednisone 5 mg PO, bid Repeat cycle every 21 days
No Known Acronym	Bloatumamide 50 mg/d PO WITH Leuprolide acetate depot 7.5 mg IM, every 28 days OR Goserelin acetate 3.6 mg implant SQ, every 28 days

Regimen	Chemotherapeutic Agent(s)
PE	Pacitaxel 120 mg/m ² by 96-hour i.v. infusion, days 1-4 Estramustine 600 mg/d PO, qd, 24 hours before pacitaxel Repeat cycle every 21 days

Single Regimens

Regimen	Chemotherapeutic Agent(s)
Estramustine	Estramustine 14 mg/kg/d PO, in 3 or 4 divided doses
Goserelin	Goserelin acetate implant 3.6 mg implant SQ 8 weeks before radiotherapy, followed by 28 days by 10.8 mg implant SQ, every 12 weeks
Nilutamide	Nilutamide 300 mg PO, days 1-30, then 150 mg PO/d in combination with surgical castration; begin on same day or day after castration
Prednisone	Prednisone 5 mg PO, bid

EXAMPLE 20 – Treatment of Multiple Myeloma

- 5 Multiple myeloma will be treated with the present complexes, e.g., with ¹⁶⁶Ho-DOTMP, in accord with the present method, employing the regimens listed on Table 9.

Table 9. Multiple Myeloma Regimens.

Combination Regimens

Regimen	Chemotherapeutic Agent(s)
M2	Vincristine 0.03 mg/kg i.v., day 1 Carmustine 0.5-1 mg/kg i.v., day 1 Cyclophosphamide 10 mg/kg i.v., day 1 Melphalan 0.25 mg/kg PO, days 1-4 OR Melphalan 0.1 mg/kg PO, days 1-7 or 1-10 Prednisone 1 mg/kg/d PO, days 1-7 Repeat cycle every 35-42 days
MP	Melphalan 8-10 mg/m ² PO, days 1-4 Prednisone 60 mg/m ² PO, days 1-4 Repeat cycle every 28-42 days

Regimen	Chemotherapeutic Agent(s)
VBMCP	Vincristine 1.2 mg/m ² i.v., day 1 Carmustine 20 mg/m ² i.v., day 1 Melphalan 8 mg/m ² PO, days 1-4 Cyclophosphamide 400 mg/m ² i.v., day 1 Prednisone 40 mg/m ² PO, days 1-7 all cycles, and 20 mg/m ² PO, days 8-14 first 3 cycles only Repeat cycle every 35 days

Single-Agent Regimens

Regimen	Chemotherapeutic Agent(s)
Dexamethasone	Dexamethasone 20 mg/m ² PO, for 4 days beginning on days 1-4, 9-12 and 17-20 Repeat cycle every 14 days
Interferon alfa-2b	Interferon alfa-2b 2 million units/m ² SQ 3 times a week for maintenance therapy in selected patients with significant response to initial chemotherapy treatment
Melphalan	Melphalan 90-140 mg/m ² i.v. Administer one cycle

The invention has been described with reference to various specific and preferred embodiments and techniques. However, it should be understood that many variations and modifications may be made while remaining within the spirit and scope of the invention.

All patents, patent applications, and literature cited in the specification are hereby incorporated by reference in their entirety. In the case of any inconsistencies, the present disclosure, including any definitions therein will prevail.
